The `CREATE TABLE` syntax is just a way to pass a command to the [InnoDB](#) engine through MySQL's SQL parser: The only things that matter are the table name `innodb_monitor` and that it be an [InnoDB](#) table. The structure of the table is not relevant at all for the [InnoDB](#) Monitor. If you shut down the server, the Monitor does not restart automatically when you restart the server. Drop the Monitor table and issue a new `CREATE TABLE` statement to start the Monitor. (This syntax may change in a future release.)

The [PROCESS](#) privilege is required to start or stop the [InnoDB](#) Monitor tables.

When you enable [InnoDB](#) Monitors for periodic output, [InnoDB](#) writes their output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, [InnoDB](#) Monitors print data about every 15 seconds. Server output usually is directed to the error log (see [Section 5.2.2, “The Error Log”](#)). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

[InnoDB](#) sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. [InnoDB](#) removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb-status-file=1` is set.

[InnoDB](#) Monitors should be enabled only when you actually want to see Monitor information because output generation does result in some performance decrement. Also, if you enable monitor output by creating the associated table, your error log may become quite large if you forget to remove the table later.

For additional information about [InnoDB](#) monitors, see:

- Mark Leith: [InnoDB Table and Tablespace Monitors](#)

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
=====
090407 12:06:19 INNODB TABLESPACE MONITOR OUTPUT
=====
```

The header for the standard Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The following sections describe the output for each Monitor.

### 13.3.14.2.1. [InnoDB](#) Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output by creating the associated [InnoDB](#) table turns on the same output stream, but the stream includes the extra information if the Lock Monitor is enabled. For example, if you create the `innodb_monitor` and `innodb_lock_monitor` tables, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor by removing the `innodb_lock_monitor` table.

Example [InnoDB](#) Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
Status:
=====
030709 13:00:59 INNODB MONITOR OUTPUT
=====
Per second averages calculated from the last 18 seconds
```

```

```

InnoDB Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to the server's error output.

Some notes on the output sections:

#### BACKGROUND THREAD

The `srv_master_thread` lines shows work done by the main background thread.

#### SEMAPHORES

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

#### LATEST FOREIGN KEY ERROR

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

#### LATEST DETECTED DEADLOCK

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 13.3.9.1, “InnoDB Lock Modes”](#).

#### TRANSACTIONS

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

#### FILE I/O

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 13.3.4, “InnoDB Startup Options and System Variables”](#).

#### INSERT BUFFER AND ADAPTIVE HASH INDEX

This section shows the status of the InnoDB insert buffer and adaptive hash index. (See [Section 13.3.11.3, “Insert Buffering”](#), and [Section 13.3.11.4, “Adaptive Hash Indexes”](#).) The contents include the number of operations performed for each, plus statistics for hash index performance.

#### LOG

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See [Section 13.3.7.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

#### BUFFER POOL AND MEMORY

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For additional information about the operation of the buffer pool, see [Section 7.9.1, “The InnoDB Buffer Pool”](#).

#### ROW OPERATIONS

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

In MySQL 5.5, output from the standard Monitor includes additional sections compared to the output for previous versions. For details, see [Section 1.4.3, “Diagnostic and Monitoring Capabilities”](#).

### 13.3.14.2.2. InnoDB Tablespace Monitor Output

The InnoDB Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. If you use individual tablespaces by enabling `innodb_file_per_table`, the Tablespace Monitor does not describe those tablespaces.

Example InnoDB Tablespace Monitor output:

```
=====
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT
=====

NUMBER of file segments: 73
Validating tablespace
Validation ok
-----
END OF INNODB TABLESPACE MONITOR OUTPUT
=====
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- `id`: The tablespace ID. A value of 0 refers to the shared tablespace.
- `size`: The current tablespace size in pages.
- `free limit`: The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.
- `free extents`: The number of free extents.
- `not full frag extents, used pages`: The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.

- `full frag extents`: The number of completely full fragment extents.
- `first seg id not used`: The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0; pages 0
```

Segment information includes these values:

`id`: The segment ID.

`space, page`: The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. `InnoDB` uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (`id`, `res`, and so forth) are derived from information in the inode.

`res`: The number of pages allocated (reserved) for the segment.

`used`: The number of allocated pages in use by the segment.

`full ext`: The number of extents allocated for the segment that are completely used.

`fragm pages`: The number of initial pages that have been allocated to the segment.

`free extents`: The number of extents allocated for the segment that are completely unused.

`not full extents`: The number of extents allocated for the segment that are partially used.

`pages`: The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and `InnoDB` allocates the first pages for it individually, up to 32 pages (this is the `fragm pages` value). After that, `InnoDB` allocates complete 64-page extents. `InnoDB` can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1; pages 14
```

It is possible for a segment that has extents allocated to it to have a `fragm pages` value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

### 13.3.14.2.3. `InnoDB` Table Monitor Output

The `InnoDB` Table Monitor prints the contents of the `InnoDB` internal data dictionary.

The output contains one section per table. The `SYS_FOREIGN` and `SYS_FOREIGN_COLS` sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created `InnoDB` table. Suppose that the following two tables have been created in the `test` database:

```
CREATE TABLE parent
(
  par_id      INT NOT NULL,
  fname       CHAR(20),
  lname       CHAR(20),
  PRIMARY KEY (par_id),
  UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id      INT NOT NULL,
  child_id    INT NOT NULL,
  name        VARCHAR(40),
  birth       DATE,
  weight      DECIMAL(10,2),
```

```

misc_info    VARCHAR(255),
last_update  TIMESTAMP,
PRIMARY KEY (par_id, child_id),
INDEX (name),
FOREIGN KEY (par_id) REFERENCES parent (par_id)
ON DELETE CASCADE
ON UPDATE CASCADE
) ENGINE = INNODB;

```

Then the Table Monitor output will look something like this (reformatted slightly):

```

=====

-----
END OF INNODB TABLE MONITOR OUTPUT
=====

```

For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in *db\_name / tbl\_name* format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The **COLUMNS** part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as **DB\_ROW\_ID** (row ID), **DB\_TRX\_ID** (transaction ID), and **DB\_ROLL\_PTR** (a pointer to the rollback/undo data).

- **DATA\_XXX**: These symbols indicate the data type. There may be multiple **DATA\_XXX** symbols for a given column.
- **prtype**: The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.
- **len**: The column length in bytes.

Each **INDEX** part of the table section provides the name and characteristics of one table index:

- **name**: The index name. If the name is **PRIMARY**, the index is a primary key. If the name is **GEN\_CLUST\_INDEX**, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-**NULL** unique index. See [Section 13.3.11.1, "Clustered and Secondary Indexes"](#).
- **id**: The index ID.
- **fields**: The number of fields in the index, as a value in *m/n* format:
  - **m** is the number of user-defined columns; that is, the number of columns you would see in the index definition in a **CREATE TABLE** statement.
  - **n** is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.
- **uniq**: The number of leading fields that are enough to determine index values uniquely.
- **type**: The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a **type** value of 3. An index with a **type** value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.
- **root page**: The index root page number.
- **appr. key vals**: The approximate index cardinality.
- **leaf pages**: The approximate number of leaf pages in the index.
- **size pages**: The approximate total number of pages in the index.
- **FIELDS**: The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal **DB\_ROW\_ID** (row ID) field. **DB\_TRX\_ID** and **DB\_ROLL\_PTR** are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the **FOREIGN KEY** definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

### 13.3.14.3. InnoDB General Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 5.2.2, "The Error Log"](#)).

- Issues relating to the [InnoDB](#) data dictionary include failed `CREATE TABLE` statements (orphaned table files), inability to open `.InnoDB` files, and `SYSTEM CANNOT FIND THE PATH SPECIFIED` errors. For information about these sorts of problems and errors, see [Section 13.3.14.4, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Use the [InnoDB](#) Monitors to obtain information about a problem (see [Section 13.3.14.2, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should use the standard Monitor to print information about the internal state of [InnoDB](#). If the problem is with locks, use the Lock Monitor. If the problem is in creation of tables or other data dictionary operations, use the Table Monitor to print the contents of the [InnoDB](#) internal data dictionary. To see tablespace information use the Tablespace Monitor.
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

### 13.3.14.4. Troubleshooting [InnoDB](#) Data Dictionary Operations

Information about table definitions is stored both in the `.frm` files, and in the [InnoDB data dictionary](#). If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

#### Problem with `CREATE TABLE`

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the [InnoDB](#) internal data dictionary, you have an orphaned table inside the [InnoDB](#) tablespace files that has no corresponding `.frm` file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

#### Problem Opening Table

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside [InnoDB](#). You can drop the orphaned `.frm` file by deleting it manually.

#### Problem with Temporary Table

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may end up with an orphaned temporary table inside the [InnoDB](#) tablespace. Using the Table Monitor, you can see listed a table with a name that begins with `#sql-`. You can perform SQL statements on tables whose name contains the character “#” if you enclose the name within backticks. Thus, you can drop such an orphaned table like any other orphaned table using the method described earlier. To copy or rename a file in the Unix shell, you need to put the

file name in double quotation marks if the file name contains “#”.

## Problem with Missing Tablespace

With `innodb_file_per_table` enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.
2. Issue `DROP TABLE` for the original table. That should successfully drop the table and `InnoDB` should print a warning to the error log that the `.ibd` file was missing.

## 13.3.15. Limits on InnoDB Tables

### Warning

Do not convert MySQL system tables in the `mysql` database from `MyISAM` to `InnoDB` tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the `mysql_install_db` script.

### Warning

It is not a good idea to configure `InnoDB` to use data files or log files on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

## Maximums and Minimums

- A table can contain a maximum of 1000 columns.
- By default, an index key for a single-column index can be up to 767 bytes. The same length limit applies to any index key prefix. See [Section 12.1.13, “CREATE INDEX Syntax”](#). For example, you might hit this limit with a `column prefix` index of more than 255 characters on a `TEXT` or `VARCHAR` column, assuming a UTF-8 character set and the maximum of 3 bytes for each character. When the `innodb_large_prefix` configuration option is enabled, this length limit is raised to 3072 bytes, for `InnoDB` tables that use the `DYNAMIC` and `COMPRESSED` row formats.

When you attempt to specify an index prefix length longer than allowed, the length is silently reduced to the maximum length. This configuration option changes the error handling for some combinations of row format and prefix length longer than the maximum allowed. See `innodb_large_prefix` for details.

- The `InnoDB` internal maximum key length is 3500 bytes, but MySQL itself restricts this to 3072 bytes. This limit applies to the length of the combined index key in a multi-column index.
- The maximum row length, except for variable-length columns (`VARBINARY`, `VARCHAR`, `BLOB` and `TEXT`), is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 13.3.12.2, “File Space Management”](#).

- Although `InnoDB` supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
```

```
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

See [Section E.10.4, “Table Column-Count and Row-Size Limits”](#).

- On some older operating systems, files must be less than 2GB. This is not a limitation of [InnoDB](#) itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one or a file large data files.
- The combined size of the [InnoDB](#) log files must be less than 4GB.
- The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.
- The default database page size in [InnoDB](#) is 16KB.

### Note

Changing the page size is not a supported operation and there is no guarantee that [InnoDB](#) will function normally with a page size other than 16KB. Problems compiling or running [InnoDB](#) may occur. In particular, [ROW\\_FORMAT=COMPRESSED](#) in the Barracuda file format assumes that the page size is at most 16KB and uses 14-bit pointers.

A version of [InnoDB](#) built for one page size cannot use data files or log files from a version built for a different page size. This limitation could affect restore or downgrade operations using data from MySQL 5.6, which does support page sizes other than 16KB.

## Index Types

- [InnoDB](#) tables do not support [FULLTEXT](#) indexes.
- [InnoDB](#) tables support spatial data types, but not indexes on them.

## Restrictions on InnoDB Tables

- [ANALYZE TABLE](#) determines index cardinality (as displayed in the [Cardinality](#) column of [SHOW INDEX](#) output) by doing eight random dives to each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of [ANALYZE TABLE](#) may produce different numbers. This makes [ANALYZE TABLE](#) fast on [InnoDB](#) tables but not 100% accurate because it does not take all rows into account.

You can change the number of random dives by modifying the [innodb\\_stats\\_sample\\_pages](#) system variable. For more information, see [Section 13.4.8, “Changes for Flexibility, Ease of Use and Reliability”](#).

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using [ANALYZE TABLE](#). In the few cases that [ANALYZE TABLE](#) does not produce values good enough for your particular tables, you can use [FORCE INDEX](#) with your queries to force the use of a particular index, or set the [max\\_seeks\\_for\\_key](#) system variable to ensure that MySQL prefers index lookups over table scans. See [Section 5.1.3, “Server System Variables”](#), and [Section C.5.6, “Optimizer-Related Issues”](#).

- [SHOW TABLE STATUS](#) does not give accurate statistics on [InnoDB](#) tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- [InnoDB](#) does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. To process a [SELECT COUNT\(\\*\) FROM t](#) statement, [InnoDB](#) scans an index of the table, which takes some time if the index is not entirely in the buffer pool. If your table does not change often, using the MySQL query cache is a good solution. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If an approximate row count is sufficient, [SHOW TABLE STATUS](#) can be used. See [Section 13.3.14.1, “InnoDB Performance Tuning Tips”](#).
- On Windows, [InnoDB](#) always stores database and table names internally in lowercase. To move databases in a binary format from

Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.

- For an `AUTO_INCREMENT` column, you must always define an index for the table, and that index must contain just the `AUTO_INCREMENT` column. In `MyISAM` tables, the `AUTO_INCREMENT` column may be part of a multiple-column index.
- While initializing a previously specified `AUTO_INCREMENT` column on a table, `InnoDB` sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. While accessing the auto-increment counter, `InnoDB` uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other clients cannot insert into the table while the `AUTO-INC` table lock is held. See [Section 13.3.5.3, “AUTO\\_INCREMENT Handling in InnoDB”](#).
- When you restart the MySQL server, `InnoDB` may reuse an old value that was generated for an `AUTO_INCREMENT` column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an `AUTO_INCREMENT` integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior, similar to how `MyISAM` works.
- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Under some conditions, `TRUNCATE tbl_name` for an `InnoDB` table is mapped to `DELETE FROM tbl_name`. See [Section 12.1.33, “TRUNCATE TABLE Syntax”](#).
- Currently, cascaded foreign key actions do not activate triggers.
- You cannot create a table with a column name that matches the name of an internal `InnoDB` column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR`, and `DB_MIX_ID`). The server reports error 1005 and refers to error -1 in the error message. This restriction applies only to use of the names in uppercase.

## Locking and Transactions

- `LOCK TABLES` acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an `InnoDB` table lock. Versions of MySQL before 4.1.2 did not acquire `InnoDB` table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no `InnoDB` table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.

As of MySQL 5.5.3, `innodb_table_locks=0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It still has an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- All `InnoDB` locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on `InnoDB` tables in `autocommit=1` mode because the acquired `InnoDB` table locks would be released immediately.
- You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.
- The limit of 1023 concurrent data-modifying transactions has been raised in MySQL 5.5 and above. The limit is now  $128 * 1023$  concurrent transactions that generate undo records. You can remove any workarounds that require changing the proper structure of your transactions, such as committing more frequently.

## 13.4. New Features of InnoDB 1.1

### 13.4.1. Introduction to InnoDB 1.1

InnoDB 1.1 combines the familiar reliability and performance of the `InnoDB` storage engine, with new performance and usability enhancements. InnoDB 1.1 includes all the features that were part of the `InnoDB` Plugin for MySQL 5.1, plus new features specific to MySQL 5.5 and higher.

Beginning with MySQL version 5.5, `InnoDB` is the default storage engine, rather than `MyISAM`, to promote greater data reliability and reducing the chance of corruption.

### 13.4.1.1. Features of the InnoDB Storage Engine

The InnoDB Storage Engine for MySQL contains several important new features:

- [Fast index creation](#): add or drop indexes without copying the data
- [Data compression](#): shrink tables, to significantly reduce storage and i/o
- [New row format](#): fully off-page storage of long `BLOB`, `TEXT`, and `VARCHAR` columns
- [File format management](#): protects upward and downward compatibility
- [INFORMATION\\_SCHEMA tables](#): information about compression and locking
- [Performance and scalability enhancements](#)
- [Other changes for flexibility, ease of use and reliability](#)

### Upward and Downward Compatibility

Note that the ability to use data compression and the new row format require the use of a new InnoDB file format called Barracuda. The previous file format, used by the built-in InnoDB in MySQL 5.1 and earlier, is now called Antelope and does not support these features, but does support the other features introduced with the InnoDB storage engine.

The InnoDB storage engine is upward compatible from standard InnoDB as built in to, and distributed with, MySQL. Existing databases can be used with the InnoDB Storage Engine for MySQL. The new parameter `innodb_file_format` can help protect upward and downward compatibility between InnoDB versions and database files, allowing users to enable or disable use of new features that can only be used with certain versions of InnoDB.

InnoDB since version 5.0.21 has a safety feature that prevents it from opening tables that are in an unknown format. However, the system tablespace may contain references to new-format tables that confuse the built-in InnoDB in MySQL 5.1 and earlier. These references are cleared in a [slow shutdown](#).

With previous versions of InnoDB, no error would be returned until you try to access a table that is in a format “too new” for the software. To provide early feedback, InnoDB 1.1 checks the system tablespace before startup to ensure that the file format used in the database is supported by the storage engine. See [Section 13.4.4.2.1, “Compatibility Check When InnoDB Is Started”](#) for the details.

### 13.4.1.2. Obtaining and Installing the InnoDB Storage Engine

Starting with MySQL 5.4.2, you do not need to do anything special to get or install the most up-to-date InnoDB storage engine. From that version forward, the InnoDB storage engine in the server is what was formerly known as the InnoDB Plugin. Earlier versions of MySQL required some extra build and configuration steps to get the Plugin-specific features such as fast index creation and table compression.

Report any bugs in the InnoDB storage engine using the [My Oracle Support site](#). For general discussions about InnoDB Storage Engine for MySQL, see <http://forums.mysql.com/list.php?22>.

### 13.4.1.3. Viewing the InnoDB Storage Engine Version Number

InnoDB storage engine releases are numbered with version numbers independent of MySQL release numbers. The initial release of the InnoDB storage engine is version 1.0, and it is designed to work with MySQL 5.1. Version 1.1 of the InnoDB storage engine is for MySQL 5.5 and up.

- The first component of the InnoDB storage engine version number designates a major release level.
- The second component corresponds to the MySQL release. The digit 0 corresponds to MySQL 5.1. The digit 1 corresponds to MySQL 5.5.
- The third component indicates the specific release of the InnoDB storage engine (at a given major release level and for a specific MySQL release); only bug fixes and minor functional changes are introduced at this level.

Once you have installed the InnoDB storage engine, you can check its version number in three ways:

- In the error log, it is printed during startup
- `SELECT * FROM information_schema.plugins;`
- `SELECT @@innodb_version;`

The InnoDB storage engine writes its version number to the error log, which can be helpful in diagnosis of errors:

```
091105 12:28:06 InnoDB Plugin 1.0.5 started; log sequence number 46509
```

Note that the `PLUGIN_VERSION` column in the table `INFORMATION_SCHEMA.PLUGINS` does not display the third component of the version number, only the first and second components, as in 1.0.

#### 13.4.1.4. Compatibility Considerations for Downgrade and Backup

**Because InnoDB 1.1 supports the “Barracuda” file format, with new on-disk data structures within both the database and log files, pay special attention to file format compatibility with respect to the following scenarios:**

- Downgrading from MySQL 5.5 to the MySQL 5.1 or earlier (without the InnoDB Plugin enabled), or otherwise using earlier versions of MySQL with database files created by MySQL 5.5 and higher.
- Using `mysqldump`.
- Using MySQL replication.
- Using MySQL Enterprise Backup or InnoDB Hot Backup.

**WARNING:** Once you create any tables with the Barracuda file format, take care to avoid crashes and corruptions when using those files with an earlier version of MySQL. It is **strongly** recommended that you use a “slow shutdown” (`SET GLOBAL innodb_fast_shutdown=0`) when stopping the MySQL server before downgrading to MySQL 5.1 or earlier. This ensures that the log files and other system information do not cause consistency issues or startup problems when using a prior version of MySQL.

**WARNING:** If you dump a database containing compressed tables with `mysqldump`, the dump file may contain `CREATE TABLE` statements that attempt to create compressed tables, or those using `ROW_FORMAT=DYNAMIC` in the new database. Therefore, be sure the new database is running the InnoDB storage engine, with the proper settings for `innodb_file_format` and `innodb_file_per_table`, if you want to have the tables re-created as they exist in the original database. Typically, when the `mysqldump` file is loaded, MySQL and InnoDB ignore `CREATE TABLE` options they do not recognize, and the table(s) are created in a format used by the running server.

**WARNING:** If you use MySQL replication, ensure all slaves are configured with the InnoDB storage engine, with the same settings for `innodb_file_format` and `innodb_file_per_table`. If you do not do so, and you create tables that require the new Barracuda file format, replication errors may occur. If a slave MySQL server is running an older version of MySQL, it ignores the `CREATE TABLE` options to create a compressed table or one with `ROW_FORMAT=DYNAMIC`, and creates the table uncompressed, with `ROW_FORMAT=COMPACT`.

**WARNING:** Version 3.0 of InnoDB Hot Backup does not support the new Barracuda file format. Using InnoDB Hot Backup Version 3 to backup databases in this format causes unpredictable behavior. MySQL Enterprise Backup, the successor product to InnoDB Hot Backup, does support tables with the Barracuda file format. You can also back up such databases with `mysqldump`.

### 13.4.2. Fast Index Creation in the InnoDB Storage Engine

In MySQL 5.5 and higher, or in MySQL 5.1 with the InnoDB Plugin, creating and dropping `secondary indexes` does not copy the contents of the entire table, making this operation much more efficient than with prior releases.

#### 13.4.2.1. Overview of Fast Index Creation

With MySQL 5.5 and higher, or MySQL 5.1 with the InnoDB Plugin, creating and dropping `secondary indexes` for InnoDB tables is much faster than before. Historically, adding or dropping an index on a table with existing data could be very slow. The `CREATE INDEX`

`DEX` and `DROP INDEX` statements worked by creating a new, empty table defined with the requested set of indexes, then copying the existing rows to the new table one-by-one, updating the indexes as the rows are inserted. After all rows from the original table were copied, the old table was dropped and the copy was renamed with the name of the original table.

The performance speedup for fast index creation applies to secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a [clustered index](#) organized based on the [primary key](#), forming what some database systems call an “index-organized table”. Because the table structure is so closely tied to the primary key, redefining the primary key still requires copying the data.

This new mechanism also means that you can generally speed the overall process of creating and loading an indexed table by creating the table with only the clustered index, and adding the secondary indexes after the data is loaded.

Although no syntax changes are required in the `CREATE INDEX` or `DROP INDEX` commands, some factors affect the performance, space usage, and semantics of this operation (see [Section 13.4.2.6, “Limitations of Fast Index Creation”](#)).

### 13.4.2.2. Examples of Fast Index Creation

It is possible to create multiple indexes on a table with one `ALTER TABLE` statement. This is relatively efficient, because the clustered index of the table needs to be scanned only once (although the data is sorted separately for each new index). For example:

```
CREATE TABLE T1(A INT PRIMARY KEY, B INT, C CHAR(1)) ENGINE=InnoDB;
INSERT INTO T1 VALUES (1,2,'a'), (2,3,'b'), (3,2,'c'), (4,3,'d'), (5,2,'e');
COMMIT;
ALTER TABLE T1 ADD INDEX (B), ADD UNIQUE INDEX (C);
```

The above statements create table `T1` with the clustered index (primary key) on column `A`, insert several rows, and then build two new indexes on columns `B` and `C`. If there were many rows inserted into `T1` before the `ALTER TABLE` statement, this approach is much more efficient than creating all the secondary indexes before loading the data.

You can also create the indexes one at a time, but then the clustered index of the table is scanned (as well as sorted) once for each `CREATE INDEX` statement. Thus, the following statements are not as efficient as the `ALTER TABLE` statement above, even though neither requires recreating the clustered index for table `T1`.

```
CREATE INDEX B ON T1 (B);
CREATE UNIQUE INDEX C ON T1 (C);
```

Dropping InnoDB secondary indexes also does not require any copying of table data. You can equally quickly drop multiple indexes with a single `ALTER TABLE` statement or multiple `DROP INDEX` statements:

```
ALTER TABLE T1 DROP INDEX B, DROP INDEX C;
```

or:

```
DROP INDEX B ON T1;
DROP INDEX C ON T1;
```

Restructuring the clustered index in InnoDB always requires copying the data in the table. For example, if you create a table without a primary key, InnoDB chooses one for you, which may be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. Defining a `PRIMARY KEY` later causes the data to be copied, as in the following example:

```
CREATE TABLE T2 (A INT, B INT) ENGINE=InnoDB;
INSERT INTO T2 VALUES (NULL, 1);
ALTER TABLE T2 ADD PRIMARY KEY (B);
```

When you create a `UNIQUE` or `PRIMARY KEY` index, InnoDB must do some extra work. For `UNIQUE` indexes, InnoDB checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, InnoDB also checks that none of the `PRIMARY KEY` columns contains a `NULL`. It is best to define the primary key when you create a table, so you need not rebuild the table later.

### 13.4.2.3. Implementation Details of Fast Index Creation

InnoDB has two types of indexes: the clustered index and secondary indexes. Since the clustered index contains the data values in its B-tree nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal InnoDB system tables and the MySQL data dictionary tables are updated to re-

flect the fact that the index no longer exists. InnoDB returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, InnoDB scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

#### 13.4.2.4. Concurrency Considerations for Fast Index Creation

While an InnoDB secondary index is being created or dropped, the table is locked in shared mode. Any writes to the table are blocked, but the data in the table can be read. When you alter the clustered index of a table, the table is locked in exclusive mode, because the data must be copied. Thus, during the creation of a new clustered index, all operations on the table are blocked.

A `CREATE INDEX` or `ALTER TABLE` statement for an InnoDB table always waits for currently executing transactions that are accessing the table to commit or roll back. `ALTER TABLE` statements that redefine an InnoDB primary key wait for all `SELECT` statements that access the table to complete, or their containing transactions to commit. No transactions whose execution spans the creation of the index can be accessing the table, because the original table is dropped when the clustered index is restructured.

Once a `CREATE INDEX` or `ALTER TABLE` statement that creates an InnoDB secondary index begins executing, queries can access the table for read access, but cannot update the table. If an `ALTER TABLE` statement is changing the clustered index for an InnoDB table, all queries wait until the operation completes.

A newly-created InnoDB secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement begins to execute. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

Because a newly-created index contains only information about data current at the time the index was created, queries that need to see data that was deleted or changed before the index was created cannot use the index. The only queries that could be affected by this limitation are those executing in transactions that began before the creation of the index was begun. For such queries, unpredictable results could occur. Newer queries can use the index.

#### 13.4.2.5. How Crash Recovery Works with Fast Index Creation

Although no data is lost if the server crashes while an `ALTER TABLE` statement is executing, the [crash recovery](#) process is different for [clustered indexes](#) and [secondary indexes](#).

If the server crashes while creating an InnoDB secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes. In the following discussion, we use the word table and clustered index interchangeably.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario. Instead, please see the InnoDB web site: <http://www.innodb.com/support/tips>.

#### 13.4.2.6. Limitations of Fast Index Creation

Take the following considerations into account when creating or dropping InnoDB indexes:

- During index creation, files are written to the temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the value of the `--tmpdir` configuration variable). Each temporary file is large enough to hold one column that makes up the new index, and each one is removed as soon as it is merged into the final index.
- The table is copied, rather than using Fast Index Creation when you create an index on a `TEMPORARY TABLE`. This has been reported as [MySQL Bug #39833](#).

- To avoid consistency issues between the InnoDB data dictionary and the MySQL data dictionary, the table is copied, rather than using Fast Index Creation when you use the `ALTER TABLE ... RENAME COLUMN` syntax.
- The statement `ALTER IGNORE TABLE t ADD UNIQUE INDEX` does not delete duplicate rows. This has been reported as [MySQL Bug #40344](#). The `IGNORE` keyword is ignored. If any duplicate rows exist, the operation fails with the following error message:

```
ERROR 23000: Duplicate entry '347' for key 'pl'
```

- As noted above, a newly-created index contains only information about data current at the time the index was created. Therefore, you should not run queries in a transaction that might use a secondary index that did not exist at the beginning of the transaction. There is no way for InnoDB to access “old” data that is consistent with the rest of the data read by the transaction. See the discussion of locking in [Section 13.4.2.4, “Concurrency Considerations for Fast Index Creation”](#).

Prior to InnoDB storage engine 1.0.4, unexpected results could occur if a query attempts to use an index created after the start of the transaction containing the query. If an old transaction attempts to access a “too new” index, InnoDB storage engine 1.0.4 and later reports an error:

```
ERROR HY000: Table definition has changed, please retry transaction
```

As the error message suggests, committing (or rolling back) the transaction, and restarting it, cures the problem.

- InnoDB storage engine 1.0.2 introduces some improvements in error handling when users attempt to drop indexes. See [section 13.4.8.6, “Better Error Handling when Dropping Indexes”](#) for details.
- MySQL 5.5 does not support efficient creation or dropping of `FOREIGN KEY` constraints. Therefore, if you use `ALTER TABLE` to add or remove a `REFERENCES` constraint, the child table is copied, rather than using Fast Index Creation.

### 13.4.3. InnoDB Data Compression

By setting InnoDB configuration options, you can create tables where the data is stored in compressed form. The compression means less data is transferred between disk and memory, and takes up less space in memory. The benefits are amplified for tables with secondary indexes, because index data is compressed also.

#### 13.4.3.1. Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are I/O-bound. Data [compression](#) enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently-used data in memory.

An InnoDB table created with `ROW_FORMAT=COMPRESSED` can use a smaller page size on disk than the usual 16KB default. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The page size is specified through the `KEY_BLOCK_SIZE` parameter. The different page size means the table must be in its own `.ibd` file rather than the system tablespace, which requires enabling the `innodb_file_per_table` option. The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, InnoDB also creates a 16KB page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

#### 13.4.3.2. Enabling Compression for a Table

The default uncompressed size of InnoDB data pages is 16KB. You can use the attributes `ROW_FORMAT=COMPRESSED`, `KEY_BLOCK_SIZE`, or both in the `CREATE TABLE` and `ALTER TABLE` statements to enable table compression. Depending on the combination of option values, InnoDB uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the `.ibd` file of the table. (The actual

compression algorithm is not affected by the `KEY_BLOCK_SIZE` value.)

### Note

Compression is applicable to tables, not to individual rows, despite the option name `ROW_FORMAT`.

To create a compressed table, you might use a statement like this:

```
CREATE TABLE name
  (column1 INT PRIMARY KEY)
  ENGINE=InnoDB
  ROW_FORMAT=COMPRESSED
  KEY_BLOCK_SIZE=4;
```

If you specify `ROW_FORMAT=COMPRESSED` but not `KEY_BLOCK_SIZE`, the default compressed page size of 8KB is used. If `KEY_BLOCK_SIZE` is specified, you can omit the attribute `ROW_FORMAT=COMPRESSED`.

Setting `KEY_BLOCK_SIZE=16` typically does not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer “overflow” pages as described in [Section 13.4.3.4, “Compressing BLOB, VARCHAR and TEXT Columns”](#).

All indexes of a table (including the clustered index) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax, and are ignored if they are specified (although you see them in the output of the `SHOW CREATE TABLE` statement).

#### 13.4.3.2.1. Configuration Parameters for Compression

Compressed tables are stored in a format that previous versions of InnoDB cannot process. To preserve downward compatibility of database files, compression can be specified only when the Barracuda data file format is enabled using the configuration parameter `innodb_file_format`.

Table compression is also not available for the InnoDB system tablespace. The system tablespace (space 0, the `ibdata*` files) may contain user data, but it also contains internal InnoDB system information, and therefore is never compressed. Thus, compression applies only to tables (and indexes) stored in their own tablespaces.

To use compression, enable the `file-per-table` mode using the configuration parameter `innodb_file_per_table` and enable the Barracuda disk file format using the parameter `innodb_file_format`. If necessary, you can set these parameters in the MySQL option file `my.cnf` or `my.ini`, or with the `SET` statement without shutting down the MySQL server.

Specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces these warnings if the Barracuda file format is not enabled. You can view them with the `SHOW WARNINGS` statement.

Level	Code	Message
Warning	1478	InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.
Warning	1478	InnoDB: KEY_BLOCK_SIZE requires innodb_file_format=1
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=4.
Warning	1478	InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table.
Warning	1478	InnoDB: assuming ROW_FORMAT=COMPACT.

### Note

These messages are only warnings, not errors, and the table is created as if the options were not specified. When InnoDB “strict mode” (see [Section 13.4.8.4, “InnoDB Strict Mode”](#)) is enabled, InnoDB generates an error, not a warning, for these cases. In strict mode, the table is not created if the current configuration does not permit using compressed tables.

The “non-strict” behavior is intended to permit you to import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.

When you import the dump file into a new database, if you want to have the tables re-created as they exist in the original database, ensure the server is running the InnoDB storage engine with the proper settings for the configuration parameters `innodb_file_format` and `innodb_file_per_table`,

### 13.4.3.2.2. SQL Compression Syntax Warnings and Errors

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

Level	Code	Message
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.

If you are running in InnoDB strict mode, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 13.4, “Meaning of `CREATE TABLE` and `ALTER TABLE` options” summarizes how the various options on `CREATE TABLE` and `ALTER TABLE` are handled.

**Table 13.4. Meaning of `CREATE TABLE` and `ALTER TABLE` options**

Option	Usage	Description
<code>ROW_FORMAT=REDUNDANT</code>	Storage format used prior to MySQL 5.0.3	Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility
<code>ROW_FORMAT=COMPACT</code>	Default storage format since MySQL 5.0.3	Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page
<code>ROW_FORMAT=DYNAMIC</code>	Available only with <code>innodb_file_format=Barracuda</code>	Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)
<code>ROW_FORMAT=COMPRESSED</code>	Available only with <code>innodb_file_format=Barracuda</code>	Compresses the table and indexes using zlib to default compressed page size of 8K bytes; implies <code>ROW_FORMAT=DYNAMIC</code>
<code>KEY_BLOCK_SIZE=n</code>	Available only with <code>innodb_file_format=Barracuda</code>	Specifies compressed page size of 1, 2, 4, 8 or 16K bytes; implies <code>ROW_FORMAT=DYNAMIC</code> and <code>ROW_FORMAT=COMPRESSED</code>

Table 13.5, “`CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When InnoDB strict mode is `OFF`, InnoDB creates or alters the table, but may ignore certain settings, as shown below. You can see the warning messages in the MySQL error log. When InnoDB strict mode is `ON`, these specified combinations of options generate errors, and the table is not created or altered. You can see the full description of the error condition with `SHOW ERRORS`. For example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.      |
| Error | 1005 | Can't create table 'test.x' (errno: 1478)  |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

**Table 13.5. `CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF**

Syntax	Warning or Error Condition	Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>
<code>ROW_FORMAT=REDUNDANT</code>	None	<code>REDUNDANT</code>
<code>ROW_FORMAT=COMPACT</code>	None	<code>COMPACT</code>
<code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or	Ignored unless both <code>innodb_file_format=Barracuda</code> and <code>in-</code>	<code>COMPACT</code>

Syntax	Warning or Error Condition	Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>
<code>KEY_BLOCK_SIZE</code> is specified	<code>nodb_file_per_table</code> are enabled	
Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)	<code>KEY_BLOCK_SIZE</code> is ignored	the requested one, or <code>COMPACT</code> by default
<code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified	None; <code>KEY_BLOCK_SIZE</code> specified is used, not the 8K default	<code>COMPRESSED</code>
<code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code> row format	<code>KEY_BLOCK_SIZE</code> is ignored	<code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code>
<code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code> , <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code>	Ignored if recognized by the MySQL parser. Otherwise, an error is issued.	<code>COMPACT</code> or N/A

When InnoDB strict mode is ON (`innodb_strict_mode=1`), the InnoDB storage engine rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of InnoDB, strict mode is not enabled by default; instead, InnoDB issues warnings (not errors) for ignored invalid parameters.

Note that it is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored by InnoDB). The real compressed page size inside InnoDB cannot be displayed by MySQL.

### 13.4.3.3. Tuning InnoDB Compression

Most often, the internal optimizations in InnoDB described in [Section 13.4.3.4, “InnoDB Data Storage and Compression”](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, there are some factors you should consider to get best performance. You need to choose which tables to compress, and what compressed page size to use. You might also adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data.

#### When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

#### Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in `CHAR`, `VARCHAR`, `TEXT` or `BLOB` columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB tables. A table and all of its indexes use the same (compressed) page size. It might be that the primary key (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in [Section 13.4.5.3, “Barracuda File Format: DYNAMIC and COMPRESSED Row Formats”](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

Experimenting is the only way to determine whether or not to compress a particular table. InnoDB compresses data in 16K chunks corresponding to the uncompressed page size, and in addition to user data, the page format includes some internal system data that is not compressed. Compression utilities compress an entire stream of data, and so may find more repeated strings across the entire input stream than InnoDB would find in a table compressed in 16K chunks. But you can get a sense of how compression efficiency by using a utility that implements LZ77 compression (such as `gzip` or WinZip) on your data file.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) and look at the size of the resulting file. When you do so (if nothing else using compression is running),

you can examine the ratio of successful compression operations to overall compression operations. (In the `INNODB_CMP` table, compare `COMPRESS_OPS` to `COMPRESS_OPS_OK`. See `INNODB_CMP` for more information.) If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.

## Compression and Application and Schema Design

Decide whether to compress data in your application or in the InnoDB table. It is usually not sensible to store data that is compressed by an application in an InnoDB compressed table. Further compression is extremely unlikely, and the attempt to compress just wastes CPU cycles.

## Compressing in the Database

The InnoDB table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

## Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

## Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed InnoDB tables) and allow InnoDB to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

## Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that InnoDB maintains for compressed data. If the updates predominantly change non-indexed columns or those containing `BLOBs` or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are `INSERTs` that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since InnoDB can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, `DELETE` operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

## Configuration Characteristics and Compression

Reading and writing database pages from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, InnoDB often uses an additional 16K in the buffer pool for an uncompressed copy of the page. The adaptive LRU algorithm in the InnoDB storage engine attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the InnoDB buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

## Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Section 13.4.3.4, “Compression of B-Tree Pages”](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the B-tree nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum InnoDB record size is around 8K, `KEY_BLOCK_SIZE=8` is usually a safe choice.

## Monitoring Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at run time, using the Information Schema tables described in [Example 13.1, “Using the Compression Information Schema Tables”](#). These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` tables report information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide, and includes summary data across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since InnoDB must split B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the InnoDB buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster CPUs, or those with more cores, can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the InnoDB buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then InnoDB is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 13.4.3.4. How Compression Works in InnoDB

This section describes some internal implementation details about compression in InnoDB. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

## Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

InnoDB implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the `.ibd` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the workload, this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization.

## InnoDB Data Storage and Compression

All user data in InnoDB is stored in pages comprising a B-tree index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) primary key and all the other columns of the table.

Secondary indexes in InnoDB are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of overflow pages used to store long [VARCHAR](#), [BLOB](#), or [TEXT](#) columns, as explained in the following sections.

## Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique InnoDB uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, InnoDB attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails, the B-tree nodes are split and the process is repeated until the update or insert succeeds.

Generally, InnoDB requires that each B-tree page can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit in uncompressed form, in the per-page modification log. Starting with InnoDB storage engine version 1.0.2, and if InnoDB strict mode is [ON](#), the InnoDB storage engine checks the maximum row size during [CREATE TABLE](#) or [CREATE INDEX](#). If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when InnoDB strict mode is [OFF](#), and a subsequent [INSERT](#) or [UPDATE](#) statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with [ALTER TABLE](#) and select a larger compressed page size ([KEY\\_BLOCK\\_SIZE](#)), shorten any column prefix indexes, or disable compression entirely with [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPACT](#).

## Compressing BLOB, VARCHAR and TEXT Columns

In a clustered index, [BLOB](#), [VARCHAR](#) and [TEXT](#) columns that are not part of the primary key may be stored on separately allocated (“overflow”) pages. We call these [off-page columns](#) whose values are stored on singly-linked lists of overflow pages.

For tables created in [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPRESSED](#), the values of [BLOB](#), [TEXT](#) or [VARCHAR](#) columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, InnoDB chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

Tables created in previous versions of InnoDB use the Antelope file format, which supports only [ROW\\_FORMAT=REDUNDANT](#) and [ROW\\_FORMAT=COMPACT](#). In these formats, InnoDB stores the first 768 bytes of [BLOB](#), [VARCHAR](#) and [TEXT](#) columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in [COMPRESSED](#) format, all data written to overflow pages is compressed “as is”; that is, InnoDB applies the zlib com-

pression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer [BLOB](#), [TEXT](#) or [VARCHAR](#) columns if the data is highly compressible, as is often the case with text data (but not previously compressed images).

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

Using a 16K compressed page size can reduce storage and I/O costs for [BLOB](#), [VARCHAR](#) or [TEXT](#) columns, because such data often compress well, and might therefore require fewer “overflow” pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form.

## Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes. To access the data in a page, InnoDB reads the compressed page from disk if it is not already in the buffer pool, then uncompresses the page to its original 16K byte form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, InnoDB may “evict” from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page may be written to disk, to free space for other data. Thus, at any given time, the buffer pool may contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

InnoDB keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that “hot” or frequently accessed data tends to stay in memory. When compressed tables are accessed, InnoDB uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an I/O-bound or CPU-bound manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, InnoDB prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

## Compression and the InnoDB Log Files

Before a compressed page is written to a database file, InnoDB writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs will always be usable, even if a future version of InnoDB uses a slightly different compression algorithm. Therefore, some increase in the size of log files, or a need for more frequent checkpoints, can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Note that the redo log file format (and the database file format) are different from previous releases when using compression. The MySQL Enterprise Backup product does support this latest Barracuda file format for compressed InnoDB tables. The older InnoDB Hot Backup product can only back up tables using the file format Antelope, and thus does not support InnoDB tables that use compression.

### 13.4.4. InnoDB File-Format Management

As InnoDB evolves, new on-disk data structures are sometimes required to support new features. Features such as compressed tables (see [Section 13.4.3, “InnoDB Data Compression”](#)), and long variable-length columns stored off-page (see [Section 13.4.5, “How InnoDB Stores Variable-Length Columns”](#)) require data file formats that are not compatible with prior versions of InnoDB. These features both require use of the new [Barracuda](#) file format.

#### Note

All other new features are compatible with the original [Antelope](#) file format and do not require the Barracuda file format.

This section discusses how to specify the file format for new InnoDB tables, compatibility of different file formats between MySQL releases,

**Named File Formats.** InnoDB 1.1 has the idea of a named file format and a configuration parameter to enable the use of features that require use of that format. The new file format is the [Barracuda](#) format, and the original InnoDB file format is called [Antelope](#). Com-

pressed tables and the new row format that stores long columns “off-page” require the use of the Barracuda file format or newer. Future versions of InnoDB may introduce a series of file formats, [identified with the names of animals](#), in ascending alphabetic order.

### 13.4.4.1. Enabling File Formats

The configuration parameter `innodb_file_format` controls whether such statements as `CREATE TABLE` and `ALTER TABLE` can be used to create tables that depend on support for the [Barracuda](#) file format.

Although Oracle recommends using the Barracuda format for new tables where practical, in MySQL 5.5 the default file format is still [Antelope](#), for maximum compatibility with replication configurations containing different MySQL releases.

The file format is a dynamic, global parameter that can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed with the `SET GLOBAL` command.

### 13.4.4.2. Verifying File Format Compatibility

InnoDB 1.1 incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an older release of the MySQL server on InnoDB data files using a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

## Backward Compatibility

Considerations of backward compatibility only apply when using a recent version of InnoDB (the InnoDB Plugin, or MySQL 5.5 and higher with InnoDB 1.1) alongside an older one (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with a prior version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB 1.1 includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with a prior version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported by the currently running software, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to an earlier file format is to copy the data to a new table, in a tablespace that uses the earlier format. This can be done with the `ALTER TABLE` statement, as described in [Section 13.4.4.4, “Downgrading the File Format”](#).

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as `'Compressed'` or `'Dynamic'`, the tablespace containing the table uses the Barracuda format. Otherwise, it uses the prior InnoDB file format, Antelope.

## Internal Details

Every InnoDB per-table tablespace (represented by a `*.ibd` file) is labeled with a file format identifier. The system tablespace (represented by the `ibdata` files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with `ROW_FORMAT=DYNAMIC`, updates the file header for the corresponding `.ibd` file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support this new file format. To protect against anomalous behavior, InnoDB version 5.0.21 and later performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in [Section 13.4.2, “Fast Index Creation in the InnoDB Storage Engine”](#).)

## Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more `ibdata` files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
- Zero or more single-table tablespaces (also called “file per table” files, named `*.ibd` files).
- InnoDB log files; usually two, `ib_logfile0` and `ib_logfile1`. Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding `.frm` files that contain metadata about InnoDB tables. The `.frm` files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

#### 13.4.4.2.1. Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., `innodb_fast_shutdown` is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check`, which is `ON` by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is `ON`, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a
file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` will be useful (with future releases of InnoDB) if you manually “downgrade” all of the tables in an ib-file set (as described in [Section 13.4.11, “Downgrading the InnoDB Storage Engine”](#)). You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a “too new” format (one that is not supported by the software you are using). If you set the configuration parameter `innodb_file_format_check` to `OFF`, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a
file format that this version doesn't support
```

#### Note

This is a very dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was a crash or “fast shutdown”. You should only set `innodb_file_format_check` to `OFF` if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs. In a future release, this parameter setting may be renamed from `OFF` to `UNSAFE`. (However, until there are newer releases of InnoDB that support additional file formats, even disabling the startup checking is in fact “safe”.)

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in [Section 13.4.4.2.2, “Compatibility Check When a Table Is Opened”](#). Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the newest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

To best illustrate this behavior, consider the scenario described in [Table 13.6, “InnoDB Data File Compatibility and Related InnoDB Parameters”](#). Imagine that some future version of InnoDB supports the Cheetah format and that an ib-file set has been used with that version.

**Table 13.6. InnoDB Data File Compatibility and Related InnoDB Parameters**

innodb file format check	innodb file format	Highest file format used in ib-file set	Highest file format supported by InnoDB	Result
OFF	Antelope or Barracuda	Barracuda	Barracuda	Database can be opened; tables can be created which require Antelope or Barracuda file format
OFF	Antelope or Barracuda	Cheetah	Barracuda	Database can be opened with a warning, since the database contains files in a “too new” format; tables can be created in Antelope or Barracuda file format; tables in Cheetah format cannot be accessed
OFF	Cheetah	Barracuda	Barracuda	Database cannot be opened; <code>innodb_file_format</code> cannot be set to Cheetah
ON	Antelope or Barracuda	Barracuda	Barracuda	Database can be opened; tables can be created in Antelope or Barracuda file format
ON	Antelope or Barracuda	Cheetah	Barracuda	Database cannot be opened, since the database contains files in a “too new” format (Cheetah)
ON	Cheetah	Barracuda	Barracuda	Database cannot be opened; <code>innodb_file_format</code> cannot be set to Cheetah

#### 13.4.4.2.2. Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses specific file formats, even if they are supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses any supported format.

As noted in [Named File Formats](#), versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in [Section 13.4.4.3, “Identifying the File Format in Use”](#).

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a “too new” format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to OFF), the table-level checking described in this section still applies.

Users are *strongly* urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the

MySQL 5.1 with the InnoDB Plugin. It is possible to “downgrade” such tables to the Antelope format with the procedure described in [Section 13.4.4.4, “Downgrading the File Format”](#).

### 13.4.4.3. Identifying the File Format in Use

After you enable a given `innodb_file_format`, this change applies only to newly created tables rather than existing ones. If you do create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required for the table’s features. For example, if you enable file format Barracuda, and create a new table that is not compressed and does not use `ROW_FORMAT=DYNAMIC`, the new tablespace that contains the table is tagged as using file format Antelope.

It is easy to identify the file format used by a given tablespace or table. The table uses the Barracuda format if the `Row_format` reported by `SHOW CREATE TABLE` or `INFORMATION_SCHEMA.TABLES` is one of ‘Compressed’ or ‘Dynamic’. (The `Row_format` is a separate column; ignore the contents of the `Create_options` column, which may contain the string `ROW_FORMAT`.) If the table in a tablespace uses neither of those features, the file uses the format supported by prior releases of InnoDB, now called file format Antelope. Then, the `Row_format` is one of ‘Redundant’ or ‘Compact’.

## Internal Details

The file format identifier is written as part of the tablespace flags (a 32-bit number) in the `*.ibd` file in the 4 bytes starting at position 54 of the file, most significant byte first. (The first byte of the file is byte zero.) On some systems, you can display these bytes in hexadecimal with the command `od -t x1 -j 54 -N 4 tablename.ibd`. If all bytes are zero, the tablespace uses the Antelope file format (which is the format used by the standard InnoDB storage engine up to version 5.1). Otherwise, the least significant bit should be set in the tablespace flags, and the file format identifier is written in the bits 5 through 11. (Divide the tablespace flags by 32 and take the remainder after dividing the integer part of the result by 128.)

### 13.4.4.4. Downgrading the File Format

Each InnoDB tablespace file (with a name matching `*.ibd`) is tagged with the file format used to create its table and indexes. The way to downgrade the tablespace is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the command:

```
ALTER TABLE t ROW_FORMAT=COMPACT;
```

on each table that you want to downgrade. The `COMPACT` row format uses the file format Antelope. It was introduced in MySQL 5.0.3.

### 13.4.4.5. Future InnoDB File Formats

The file format used by the standard built-in InnoDB in MySQL 5.1 is the [Antelope](#) format. The file format introduced with InnoDB Plugin 1.0 is the [Barracuda](#) format. Although no new features have been announced that would require additional new file formats, the InnoDB file format mechanism allows for future enhancements.

For the sake of completeness, these are the file format names that might be used for future file formats: Antelope, Barracuda, Cheetah, Dragon, Elk, Fox, Gazelle, Hornet, Impala, Jaguar, Kangaroo, Leopard, Moose, Nautilus, Ocelot, Porpoise, Quail, Rabbit, Shark, Tiger, Urchin, Viper, Whale, Xenops, Yak and Zebra. These file formats correspond to the internal identifiers 0..25.

## 13.4.5. How InnoDB Stores Variable-Length Columns

This section discusses how certain InnoDB features, such as table [compression](#) and off-page storage of long columns, are controlled by the `ROW_FORMAT` clause of the `CREATE TABLE` statement. It discusses considerations for choosing the right row format and compatibility of row formats between MySQL releases.

### 13.4.5.1. Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk page, queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

All data in InnoDB is stored in database pages that make up a [B-tree index](#) (the [clustered index](#) organized according to the [primary key](#) columns). Table data and indexes both use this type of structure. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as [BLOB](#) and [VARCHAR](#) that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#). We call such columns [off-page column](#). The values of these columns are stored on singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases,

all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The [Barracuda](#) file format provides a new option ([KEY\\_BLOCK\\_SIZE](#)) to control how much column data is stored in the clustered index, and how much is placed on overflow pages.

### 13.4.5.2. Specifying the Row Format for a Table

You specify the row format for a table with the [ROW\\_FORMAT](#) clause of the [CREATE TABLE](#) and [ALTER TABLE](#) statements.

### 13.4.5.3. Barracuda File Format: [DYNAMIC](#) and [COMPRESSED](#) Row Formats

When [innodb\\_file\\_format](#) is set to Barracuda and a table is created with [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPRESSED](#), long column values are stored fully off-page, and the clustered index record contains only a 20-byte pointer to the overflow page.

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, InnoDB chooses the longest columns for off-page storage until the clustered index record fits on the B-tree page.

The [DYNAMIC](#) row format maintains the efficiency of storing the entire row in the index node if it fits (as do the [COMPACT](#) and [REDUNDANT](#) formats), but this new format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The [DYNAMIC](#) format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With [DYNAMIC](#) format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The [COMPRESSED](#) row format uses similar internal details for off-page storage as the [DYNAMIC](#) row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. For full details about the [COMPRESSED](#) row format, see [Section 13.4.3, “InnoDB Data Compression”](#).

### 13.4.5.4. Antelope File Format: [COMPACT](#) and [REDUNDANT](#) Row Formats

Early versions of InnoDB used an unnamed file format (now called [Antelope](#)) for database files. With that format, tables were defined with [ROW\\_FORMAT=COMPACT](#) (or [ROW\\_FORMAT=REDUNDANT](#)) and InnoDB stored up to the first 768 bytes of variable-length columns (such as [BLOB](#) and [VARCHAR](#)) in the index record within the B-tree node, with the remainder stored on the overflow pages.

To preserve compatibility with those prior versions, tables created with the newest InnoDB use the prefix format, unless one of [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPRESSED](#) is specified (or implied) on the [CREATE TABLE](#) statement.

With the Antelope file format, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the B-tree node. This works well for relatively short [BLOB](#)s, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many [BLOB](#) columns could cause B-tree nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

## 13.4.6. InnoDB [INFORMATION\\_SCHEMA](#) tables

The [INFORMATION\\_SCHEMA](#) is a MySQL feature that helps you monitor server activity to diagnose capacity and performance issues. Several InnoDB-related [INFORMATION\\_SCHEMA](#) tables ([INNODB\\_CMP](#), [INNODB\\_CMP\\_RESET](#), [INNODB\\_CMPMEM](#), [INNODB\\_CMPMEM\\_RESET](#), [INNODB\\_TRX](#), [INNODB\\_LOCKS](#) and [INNODB\\_LOCK\\_WAITS](#)) contain live information about compressed InnoDB tables, the compressed InnoDB buffer pool, all transactions currently executing inside InnoDB, the locks that transactions hold and those that are blocking transactions waiting for access to a resource (a table or row).

The Information Schema tables are themselves plugins to the MySQL server, and must be activated by [INSTALL](#) statements. If they are installed, but the InnoDB storage engine plugin is not installed, these tables appear to be empty.

This section describes the InnoDB-related Information Schema tables and shows some examples of their use.

### 13.4.6.1. Information Schema Tables about Compression

Two new pairs of Information Schema tables provided by the InnoDB storage engine can give you some insight into how well compression is working overall. One pair of tables contains information about the number of compression operations and the amount of time spent performing compression. Another pair of tables contains information on the way memory is allocated for compression.

#### 13.4.6.1.1. [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#)

The tables `INNODB_CMP` and `INNODB_CMP_RESET` contain status information on the operations related to compressed tables, which are covered in [Section 13.4.3, “InnoDB Data Compression”](#). The compressed page size is in the column `PAGE_SIZE`.

These two tables have identical contents, but reading from `INNODB_CMP_RESET` resets the statistics on compression and uncompression operations. For example, if you archive the output of `INNODB_CMP_RESET` every 60 minutes, you see the statistics for each hourly period. If you monitor the output of `INNODB_CMP` (making sure never to read `INNODB_CMP_RESET`), you see the cumulated statistics since InnoDB was started.

For the table definition, see [Table 19.1, “Columns of `INNODB\_CMP` and `INNODB\_CMP\_RESET`”](#).

#### 13.4.6.1.2. `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET`

The tables `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` contain status information on the compressed pages that reside in the buffer pool. Please consult [Section 13.4.3, “InnoDB Data Compression”](#) for further information on compressed tables and the use of the buffer pool. The tables `INNODB_CMP` and `INNODB_CMP_RESET` should provide more useful statistics on compression.

#### Internal Details

The InnoDB storage engine uses a so-called “buddy allocator” system to manage memory allocated to pages of various sizes, from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

These two tables have identical contents, but reading from `INNODB_CMPMEM_RESET` resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of `INNODB_CMPMEM_RESET`, it would show the hourly statistics. If you never read `INNODB_CMPMEM_RESET` and monitored the output of `INNODB_CMPMEM` instead, it would show the cumulated statistics since InnoDB was started.

For the table definition, see [Table 19.2, “Columns of `INNODB\_CMPMEM` and `INNODB\_CMPMEM\_RESET`”](#).

#### 13.4.6.1.3. Using the Compression Information Schema Tables

##### Example 13.1. Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 13.4.3, “InnoDB Data Compression”](#), `INNODB_CMP`, and `INNODB_CMPMEM`).

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMP` under light load. The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

page size	compress ops	compress ops ok	compress time	uncompress ops	uncompress time
1024	0	0	0	0	0
2048	0	0	0	0	0
4096	0	0	0	0	0
8192	1048	921	0	61	0
16384	0	0	0	0	0

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the buffer pool.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under light load. We can see that some memory is unusable due to fragmentation of the InnoDB memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low, because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

page size	pages used	pages free	relocation ops	relocation time
1024	0	0	0	0
2048	0	1	0	0
4096	0	1	0	0

page size	pages used	pages free	relocation ops	relocation time
8192	6169	0	5	0
16384	0	0	0	0

### 13.4.6.2. Information Schema Tables about Transactions

Three InnoDB-related Information Schema tables make it easy to monitor transactions and diagnose possible locking problems. The three tables are `INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`.

#### 13.4.6.2.1. `INNODB_TRX`

Contains information about every transaction currently executing inside InnoDB, including whether the transaction is waiting for a lock, when the transaction started, and the particular SQL statement the transaction is executing.

For the table definition, see [Table 19.3, “INNODB\\_TRX Columns”](#).

#### 13.4.6.2.2. `INNODB_LOCKS`

Each transaction in InnoDB that is waiting for another transaction to release a lock (`INNODB_TRX.TRX_STATE = 'LOCK WAIT'`) is blocked by exactly one “blocking lock request”. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. The waiting or blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, `INNODB_LOCKS` contains one row that describes each lock the transaction has requested, and for which it is waiting. `INNODB_LOCKS` also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock (`'RUNNING'`, `'LOCK WAIT'`, `'ROLLING BACK'` or `'COMMITTING'`). The lock that is blocking a transaction is always held in a mode (read vs. write, shared vs. exclusive) incompatible with the mode of requested lock.

For the table definition, see [Table 19.4, “INNODB\\_LOCKS Columns”](#).

#### 13.4.6.2.3. `INNODB_LOCK_WAITS`

Using this table, you can tell which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each *blocked* transaction, indicating the lock it has requested and the lock(s) that is (are) blocking that request. The `REQUESTED_LOCK_ID` refers to the lock that a transaction is requesting, and the `BLOCKING_LOCK_ID` refers to the lock (held by another transaction) that is preventing the first transaction from proceeding. For any given blocked transaction, all rows in `INNODB_LOCK_WAITS` have the same value for `REQUESTED_LOCK_ID` and different values for `BLOCKING_LOCK_ID`.

For the table definition, see [Table 19.5, “INNODB\\_LOCK\\_WAITS Columns”](#).

### 13.4.6.2.4. Using the Transaction Information Schema Tables

#### Example 13.2. Identifying Blocking Transactions

It is sometimes helpful to be able to identify which transaction is blocking another. You can use the Information Schema tables to find out which transaction is waiting for another, and which resource is being requested.

Suppose you have the following scenario, with three users running concurrently. Each user (or session) corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these users have issued the following commands, but none has yet committed its transaction:

- **User A:**

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- **User B:**

```
SELECT b FROM t FOR UPDATE;
```

- User C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, you may use this query to see who is waiting for whom:

```
SELECT r.trx_id waiting_trx_id,
       r.trx_mysql_thread_id waiting_thread,
       r.trx_query waiting_query,
       b.trx_id blocking_trx_id,
       b.trx_mysql_thread_id blocking_thread,
       b.trx_query blocking_query
FROM   information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b ON
        b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r ON
        r.trx_id = w.requesting_trx_id;
```

waiting trx id	waiting thread	waiting query	blocking trx id	blocking thread	blocking query
A4	6	SELECT b FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A4	6	SELECT b FROM t FOR UPDATE

In the above result, you can identify users by the “waiting query” or “blocking query”. As you can see:

- User B (trx id 'A4', thread 6) and User C (trx id 'A5', thread 7) are both waiting for User A (trx id 'A3', thread 5).
- User C is waiting for User B as well as User A.

You can see the underlying data in the tables `INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`.

The following table shows some sample Contents of `INFORMATION_SCHEMA.INNODB_TRX`.

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
A3	RUN- NING	2008-01-15 16:44:54	NULL	NULL	2	5	SELECT SLEEP(100)
A4	LOCK WAIT	2008-01-15 16:45:09	A4:1:3:2	2008-01-15 16:45:09	2	6	SELECT b FROM t FOR UPDATE
A5	LOCK WAIT	2008-01-15 16:45:14	A5:1:3:2	2008-01-15 16:45:14	2	7	SELECT c FROM t FOR UPDATE

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCKS`.

lock id	lock trx id	lock mode	lock type	lock table	lock index	lock space	lock page	lock rec	lock data
A3:1:3:2	A3	X	RECORD	`test`.`t`	`PRIMARY`	1	3	2	0x0200
A4:1:3:2	A4	X	RECORD	`test`.`t`	`PRIMARY`	1	3	2	0x0200
A5:1:3:2	A5	X	RECORD	`test`.`t`	`PRIMARY`	1	3	2	0x0200

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCK_WAITS`.

requesting trx id	requested lock id	blocking trx id	blocking lock id
A4	A4:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A3	A3:1:3:2

requesting trx id	requested lock id	blocking trx id	blocking lock id
A5	A5:1:3:2	A4	A4:1:3:2

### Example 13.3. More Complex Example of Transaction Data in Information Schema Tables

Sometimes you would like to correlate the internal InnoDB locking information with session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB transaction ID, the corresponding MySQL session ID and name of the user that may be holding a lock, and thus blocking another transaction.

The following output from the `INFORMATION_SCHEMA` tables is taken from a somewhat loaded system.

As can be seen in the following tables, there are several transactions running.

The following `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables shows that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D` and `77B` to commit.
- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.
- Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.
- Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.
- Transaction `77A` is running, currently executing `SELECT`.
- Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.
- Transaction `E55` (executing an `INSERT`) is waiting for transaction `19C` to commit.
- Transaction `19C` is running, currently executing an `INSERT`.

Note that there may be an inconsistency between queries shown in the two tables `INNODB_TRX.TRX_QUERY` and `PROCESSLIST.INFO`. The current transaction ID for a thread, and the query being executed in that transaction, may be different in these two tables for any given thread. See [Section 13.4.6.3.3, “Possible Inconsistency with PROCESSLIST”](#) for an explanation.

The following table shows the contents of `INFORMATION_SCHEMA.PROCESSLIST` in a loaded system.

ID	USER	HOST	DB	COMMAND	TIME	STATE	INFO
384	root	localhost	test	Query	10	update	insert into t2 values ...
257	root	localhost	test	Query	3	update	insert into t2 values ...
130	root	localhost	test	Query	0	update	insert into t2 values ...
61	root	localhost	test	Query	1	update	insert into t2 values ...
8	root	localhost	test	Query	1	update	insert into t2 values ...
4	root	localhost	test	Query	0	preparing	SELECT * FROM processlist
2	root	localhost	test	Sleep	566		NULL

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_TRX` in a loaded system.

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
77F	LOCK WAIT	2008-01-15 13:10:16	77F:806	2008-01-15 13:10:16	1	876	insert into t09 (D, B, C) values ...
77E	LOCK WAIT	2008-01-15 13:10:16	77E:806	2008-01-15 13:10:16	1	875	insert into t09 (D, B, C) values ...
77D	LOCK WAIT	2008-01-15 13:10:16	77D:806	2008-01-15 13:10:16	1	874	insert into t09 (D, B, C) values ...
77B	LOCK WAIT	2008-01-15 13:10:16	77B:733:12:1	2008-01-15 13:10:16	4	873	insert into t09 (D, B, C) values ...
77A	RUN-NI NG	2008-01-15 13:10:16	NULL	NULL	4	872	select b, c from t09 where ...
E56	LOCK WAIT	2008-01-15 13:10:06	E56:743:6:2	2008-01-15 13:10:06	5	384	insert into t2 val- ues ...
E55	LOCK WAIT	2008-01-15 13:10:06	E55:743:38:2	2008-01-15 13:10:13	965	257	insert into t2 val- ues ...
19C	RUN-NI NG	2008-01-15 13:09:10	NULL	NULL	2900	130	insert into t2 val- ues ...

### 13.4.6.3. Special Locking Considerations for InnoDB `INFORMATION_SCHEMA` Tables

#### 13.4.6.3.1. Understanding InnoDB Locking

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks transactions hold. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may be requesting a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or rollback. If a transaction is not waiting for a lock, it is in the `'RUNNING'` state. If a transaction is waiting for a lock, it is in the `'LOCK WAIT'` state.

The table `INNODB_LOCKS` holds one or more row for each `'LOCK WAIT'` transaction, indicating the lock request(s) that is (are) preventing its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The table `INNODB_LOCK_WAITS` shows which locks already held by a transaction are blocking locks requested by other transactions.

#### 13.4.6.3.2. Granularity of `INFORMATION_SCHEMA` Data

The data exposed by the transaction and locking tables represent a glimpse into fast-changing data. This is not like other (user) tables, where the data only changes when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading `JOINS` between the `INFORMATION_SCHEMA` tables, InnoDB collects the required transaction and locking information into an intermediate buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time “snapshot”. If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you `JOIN` any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the `PROCESS` privilege are allowed to `SELECT` from them.

#### 13.4.6.3.3. Possible Inconsistency with `PROCESSLIST`

As just described, while the transaction and locking data is correct and consistent when these `INFORMATION_SCHEMA` tables are pop-

ulated, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in sync. Thus, you should be careful in comparing the data in the InnoDB transaction and locking tables with that in the [MySQL table `PROCESSLIST`](#). The data from the [PROCESSLIST](#) table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single [SELECT](#) ([JOINING `INNODB\_TRX` and `PROCESSLIST`](#), for example), the content of those tables is generally not consistent. [INNODB\\_TRX](#) may reference rows that are not present in [PROCESSLIST](#) or the currently executing SQL query of a transaction, shown in [INNODB\\_TRX . TRX\\_QUERY](#) may be different from the one in [PROCESSLIST . INFO](#). The query in [INNODB\\_TRX](#) is always consistent with the rest of [INNODB\\_TRX](#), [INNODB\\_LOCKS](#) and [INNODB\\_LOCK\\_WAITS](#) when the data comes from the same snapshot.

## 13.4.7. InnoDB Performance and Scalability Enhancements

This section discusses recent InnoDB enhancements to performance and scalability, covering the performance features in InnoDB 1.1 with MySQL 5.5, and the features in the InnoDB Plugin for MySQL 5.1. This information is useful to any DBA or developer who is concerned with performance and scalability. Although some of the enhancements do not require any action on your part, knowing this information can still help you diagnose performance issues more quickly and modernize systems and applications that rely on older, inefficient behavior.

### 13.4.7.1. Overview of InnoDB Performance

InnoDB has always been highly efficient, and includes several unique architectural elements to assure high performance and scalability. The latest InnoDB storage engine includes new features that take advantage of advances in operating systems and hardware platforms, such as multi-core processors and improved memory allocation systems. In addition, new configuration options let you better control some InnoDB internal subsystems to achieve the best performance with your workload.

Starting with MySQL 5.5 and InnoDB 1.1, the built-in InnoDB storage engine within MySQL is upgraded to the full feature set and performance of the former InnoDB Plugin. This change makes these performance and scalability enhancements available to a much wider audience than before, and eliminates the separate installation step of the InnoDB Plugin. After learning about the InnoDB performance features in this section, continue with [Chapter 7, \*Optimization\*](#) to learn the best practices for overall MySQL performance, and [Section 7.5, “Optimizing for InnoDB Tables”](#) in particular for InnoDB tips and guidelines.

### 13.4.7.2. Faster Locking for Improved Scalability

In MySQL and InnoDB, multiple threads of execution access shared data structures. InnoDB synchronizes these accesses with its own implementation of [mutexes](#) and [read/write locks](#). InnoDB has historically protected the internal state of a read/write lock with an InnoDB mutex. On Unix and Linux platforms, the internal state of an InnoDB mutex is protected by a [Pthreads](#) mutex, as in IEEE Std 1003.1c (POSIX.1c).

On many platforms, there is a more efficient way to implement mutexes and read/write locks. [Atomic](#) operations can often be used to synchronize the actions of multiple threads more efficiently than Pthreads. Each operation to acquire or release a lock can be done in fewer CPU instructions, and thus result in less wasted time when threads are contending for access to shared data structures. This in turn means greater scalability on multi-core platforms.

InnoDB implements mutexes and read/write locks with the [built-in functions provided by the GNU Compiler Collection \(GCC\) for atomic memory access](#) instead of using the Pthreads approach previously used. More specifically, an InnoDB that is compiled with GCC version 4.1.2 or later uses the atomic builtins instead of a `pthread_mutex_t` to implement InnoDB mutexes and read/write locks.

On 32-bit Microsoft Windows, InnoDB has implemented mutexes (but not read/write locks) with hand-written assembler instructions. Beginning with Microsoft Windows 2000, functions for [Interlocked Variable Access](#) are available that are similar to the built-in functions provided by GCC. On Windows 2000 and higher, InnoDB makes use of the Interlocked functions. Unlike the old hand-written assembler code, the new implementation supports read/write locks and 64-bit platforms.

Solaris 10 introduced library functions for [atomic operations](#), and InnoDB uses these functions by default. When MySQL is compiled on Solaris 10 with a compiler that does not support the [built-in functions provided by the GNU Compiler Collection \(GCC\) for atomic memory access](#), InnoDB uses the library functions.

This change improves the scalability of InnoDB on multi-core systems. This feature is enabled out-of-the-box on the platforms where it is supported. You do not have to set any parameter or option to take advantage of the improved performance. On platforms where the GCC, Windows, or Solaris functions for atomic memory access are not available, InnoDB uses the traditional Pthreads method of implementing mutexes and read/write locks.

When MySQL starts, InnoDB writes a message to the log file indicating whether atomic memory access is used for mutexes, for mutexes and read/write locks, or neither. If suitable tools are used to build InnoDB and the target CPU supports the atomic operations required, InnoDB uses the built-in functions for mutexing. If, in addition, the compare-and-swap operation can be used on thread identifiers (`pthread_t`), then InnoDB uses the instructions for read-write locks as well.

Note: If you are building from source, ensure that the build process properly takes advantage of your platform capabilities.

For more information about the performance implications of locking, see [Section 7.10, “Optimizing Locking Operations”](#).

### 13.4.7.3. Using Operating System Memory Allocators

When InnoDB was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, InnoDB implemented its own memory allocator in the `mem` subsystem. This allocator is guarded by a single mutex, which may become a [bottleneck](#). InnoDB also implements a wrapper interface around the system allocator (`malloc` and `free`) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. New memory allocators perform better and are more scalable than they were in the past. The leading high-performance memory allocators include [Hoard](#), [libumem](#), [mtmalloc](#), [ptmalloc](#), [tbbmalloc](#), and [TCMalloc](#). Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, InnoDB-specific memory allocator.

You can control whether InnoDB uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter `innodb_use_sys_malloc` in the MySQL option file (`my.cnf` or `my.ini`). If set to `ON` or `1` (the default), InnoDB uses the `malloc` and `free` functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the InnoDB memory allocator, set `innodb_use_sys_malloc` to `0`.

#### Note

When the InnoDB memory allocator is disabled, InnoDB ignores the value of the parameter `innodb_additional_mem_pool_size`. The InnoDB memory allocator uses an additional memory pool for satisfying allocation requests without having to fall back to the system memory allocator. When the InnoDB memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable `LD_PRELOAD` or `LD_LIBRARY_PATH` point to the dynamic library that implements the allocator. On other systems, some relinking may be necessary. Please refer to the documentation of the memory allocator library of your choice.

Since InnoDB cannot track all memory use when the system memory allocator is used (`innodb_use_sys_malloc` is `ON`), the section “BUFFER POOL AND MEMORY” in the output of the `SHOW ENGINE INNODB STATUS` command only includes the buffer pool statistics in the “Total memory allocated”. Any memory allocated using the `mem` subsystem or using `ut_malloc` is excluded.

For more information about the performance implications of InnoDB memory usage, see [Section 7.9, “Buffering and Caching”](#).

### 13.4.7.4. Controlling InnoDB Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are done to a table, often the values of indexed columns (particularly the values of secondary keys) are not in sorted order, requiring substantial I/O to bring secondary indexes up to date. InnoDB has an [insert buffer](#) that caches changes to secondary index entries when the relevant page is not in the [buffer pool](#), thus avoiding I/O operations by not reading in the page from the disk. The buffered changes are merged when the page is loaded to the buffer pool, and the updated page is later flushed to disk using the normal mechanism. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a [slow shutdown](#).

Because it can result in fewer disk reads and writes, this feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the insert buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable insert buffering. If the working set entirely fits in the buffer pool, insert buffering does not impose any extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which InnoDB performs insert buffering with the system configuration parameter `innodb_change_buffering`. You can turn on and off buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is represented as a combination of an insert and a delete. In MySQL 5.5 and higher, the default value is changed from `inserts` to `all`.

The allowed values of `innodb_change_buffering` are:

- **all**

The default value: buffer inserts, delete-marking operations, and purges.

- **none**

Do not buffer any operations.

- **inserts**

Buffer insert operations.

- **deletes**

Buffer delete-marking operations.

- **changes**

Buffer both inserts and delete-marking.

- **purges**

Buffer the physical deletion operations that happen in the background.

You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege. Changing the setting affects the buffering of new operations; the merging of already buffered entries is not affected.

For more information about speeding up `INSERT`, `UPDATE`, and `DELETE` statements, see [Section 7.2.2, “Optimizing DML Statements”](#).

### 13.4.7.5. Controlling Adaptive Hash Indexing

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use [hash indexes](#) rather than [B-tree](#) lookups. MySQL monitors searches on each index defined for an InnoDB table. If it notices that certain index values are being accessed frequently, it automatically builds an in-memory hash table for that index. Based on the observed pattern of searches, it builds a hash index using a prefix of the index key. The prefix of the key can be any length, and it may be that only some of the values in the B-tree appear in the hash index. Hash indexes are built on demand for those pages of the index that are often accessed.

This [adaptive hash index](#) mechanism allows InnoDB to take advantage of large amounts of memory, something typically done only by database systems specifically designed for databases that reside entirely in memory. Normally, the automatic building and use of adaptive hash indexes improves performance. However, sometimes, the read/write lock that guards access to the adaptive hash index may become a source of contention under heavy workloads, such as multiple concurrent joins.

You can monitor the use of the adaptive hash index and the contention for its use in the “SEMAPHORES” section of the output of the `SHOW ENGINE INNODB STATUS` command. If you see many threads waiting on an RW-latch created in `btr0sea.c`, then it might be useful to disable adaptive hash indexing.

The configuration parameter `innodb_adaptive_hash_index` can be set to disable or enable the adaptive hash index. See [Section 13.4.8.2.4, “Dynamically Changing `innodb\_adaptive\_hash\_index`”](#) for details.

For more information about the performance characteristics of hash indexes, see [Section 7.3.8, “Comparison of B-Tree and Hash Indexes”](#).

### 13.4.7.6. Changes Regarding Thread Concurrency

InnoDB uses operating system [threads](#) to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up reduce the need to limit the number of concurrently executing threads inside InnoDB.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new re-

quest sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. Currently, the default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads, as shown in Table 13.7, “Changes to `innodb_thread_concurrency`”.

**Table 13.7. Changes to `innodb_thread_concurrency`**

InnoDB Version	MySQL Version	Default value	Default limit of concurrent threads	Value to allow unlimited threads
Built-in	Earlier than 5.1.11	20	No limit	20 or higher
Built-in	5.1.11 and newer	8	8	0
InnoDB before 1.0.3	(corresponding to Plugin)	8	8	0
InnoDB 1.0.3 and newer	(corresponding to Plugin)	0	No limit	0

Note that InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads, InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a single SQL statement to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB. If the tickets run out, `innodb_thread_concurrency` is observed again and further tickets are assigned. The number of tickets to assign is specified by the global option `innodb_concurrency_tickets`, which is 500 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_use_sys_malloc` and `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see Section 7.11.5.1, “How MySQL Uses Threads for Client Connections”.

### 13.4.7.7. Changes in the Read-Ahead Algorithm

A **read-ahead** request is an I/O request to prefetch multiple pages in the **buffer pool** asynchronously, in anticipation that these pages will be needed soon. InnoDB uses or has used two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is based on the access pattern of the pages in the buffer pool, not just their number. You can control when InnoDB performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read in the last page of the current extent.

**Random** read-ahead is a former technique that has now been removed as of MySQL 5.5. If a certain number of pages from the same extent (64 consecutive pages) were found in the buffer pool, InnoDB asynchronously issued a request to prefetch the remaining pages of the extent. Random read-ahead added unnecessary complexity to the InnoDB code and often resulted in performance degradation rather than improvement. This feature is no longer part of InnoDB, and users should generally see equivalent or improved performance.

If the number of pages read from an extent of 64 pages is greater or equal to `innodb_read_ahead_threshold`, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. Thus, this parameter controls how sensitive InnoDB is to the pat-

tern of page accesses within an extent in deciding whether to read the following extent asynchronously. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, InnoDB triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, InnoDB would trigger an asynchronous read-ahead even if as few as 8 pages in the extent were accessed sequentially.

The new configuration parameter `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56, meaning that an asynchronous read-ahead is performed only when 56 of the 64 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`), or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. See [Section 13.4.8.8, “More Read-Ahead Statistics”](#) for more information.

For more information about I/O performance, see [Section 7.5.7, “Optimizing InnoDB Disk I/O”](#) and [Section 7.11.3, “Optimizing Disk I/O”](#).

### 13.4.7.8. Multiple Background I/O Threads

InnoDB uses background [threads](#) to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages, using the configuration parameters `innodb_read_io_threads` and `innodb_write_io_threads`. These parameters signify the number of background threads used for read and write requests respectively. They are effective on all supported platforms. You can set the value of these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change them dynamically. The default value for these parameters is 4 and the permissible values range from 1-64.

These parameters replace `innodb_file_io_threads` from earlier versions of MySQL. If you try to set a value for this obsolete parameter, a warning is written to the log file and the value is ignored. This parameter only applied to Windows platforms. (On non-Windows platforms, there was only one thread each for read and write.)

The purpose of this change is to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is the [read-ahead](#) requests. InnoDB tries to balance the load of incoming requests in such way that most of the background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread to increase the chances of coalescing the requests together. If you have a high end I/O subsystem and you see more than  $64 \times \text{innodb\_read\_io\_threads}$  pending read requests in `SHOW ENGINE INNODB STATUS`, you might gain by increasing the value of `innodb_read_io_threads`.

For more information about InnoDB I/O performance, see [Section 7.5.7, “Optimizing InnoDB Disk I/O”](#).

### 13.4.7.9. Asynchronous I/O on Linux

Starting in InnoDB 1.1 with MySQL 5.5, the [asynchronous I/O](#) capability that InnoDB has had on Windows systems is now available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in the output of the command `SHOW ENGINE INNODB STATUS\G`.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you can fix the error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

In general, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, set the option `innodb_use_native_aio=0` in the configuration file. This new configuration option applies to Linux systems only, and cannot be changed once the server is running.

For more information about InnoDB I/O performance, see [Section 7.5.7, “Optimizing InnoDB Disk I/O”](#).

### 13.4.7.10. Group Commit

InnoDB, like any other [ACID](#)-compliant database engine, flushes the [redo log](#) of a transaction before it is committed. Historically, InnoDB used [group commit](#) functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, InnoDB issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

Group commit in InnoDB worked until MySQL 4.x, and works once again with MySQL 5.1 with the InnoDB Plugin, and MySQL 5.5

and higher. The introduction of support for the distributed transactions and Two Phase Commit (2PC) in MySQL 5.0 interfered with the InnoDB group commit functionality. This issue is now resolved.

The group commit functionality inside InnoDB works with the Two Phase Commit protocol in MySQL. Re-enabling of the group commit functionality fully ensures that the ordering of commit in the MySQL binlog and the InnoDB logfile is the same as it was before. It means it is **totally safe to use MySQL Enterprise Backup with InnoDB 1.0.4** (that is, the InnoDB Plugin with MySQL 5.1) and above. When the binlog is enabled, you typically also set the configuration option `sync_binlog=0`, because group commit for the binary log is only supported if it is set to 0.

Group commit is transparent; you do not need to do anything to take advantage of this significant performance improvement.

For more information about performance of `COMMIT` and other transactional operations, see [Section 7.5.2, “Optimizing InnoDB Transaction Management”](#).

### 13.4.7.11. Controlling the Master Thread I/O Rate

The [master thread](#) in InnoDB is a thread that performs various tasks in the background. Most of these tasks are I/O related, such as flushing dirty pages from the buffer pool or writing changes from the insert buffer to the appropriate secondary indexes. The master thread attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the free I/O bandwidth available and tune its activities to take advantage of this free capacity. Historically, InnoDB has used a hard coded value of 100 IOPs (input/output operations per second) as the total I/O capacity of the server.

The parameter `innodb_io_capacity` indicates the overall I/O capacity available to InnoDB. This parameter should be set to approximately the number of I/O operations that the system can perform per second. The value depends on your system configuration. When `innodb_io_capacity` is set, the master threads estimates the I/O bandwidth available for background tasks based on the set value. Setting the value to `100` reverts to the old behavior.

You can set the value of `innodb_io_capacity` to any number 100 or greater. The default value is `200`, reflecting that the performance of typical modern I/O devices is higher than in the early days of MySQL. Typically, values around the previous default of 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and SSDs benefit from higher values.

You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

For more information about InnoDB I/O performance, see [Section 7.5.7, “Optimizing InnoDB Disk I/O”](#).

### 13.4.7.12. Controlling the Flushing Rate of Dirty Pages

InnoDB performs certain tasks in the background, including [flushing](#) of [dirty pages](#) (those pages that have been changed but are not yet written to the database files) from the [buffer pool](#), a task performed by the [master thread](#). Currently, InnoDB aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool exceeds `innodb_max_dirty_pages_pct`.

InnoDB uses a new algorithm to estimate the required rate of flushing, based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that buffer flush activity keeps up with the need to keep the buffer pool “clean”. Automatically adjusting the rate of flushing can help to avoid steep dips in throughput, when excessive buffer pool flushing limits the I/O capacity available for ordinary read and write activity.

InnoDB uses its log files in a circular fashion. Before reusing a portion of a log file, InnoDB flushes to disk all dirty buffer pool pages whose redo entries are contained in that portion of the log file, a process known as a [sharp checkpoint](#). If a workload is write-intensive, it generates a lot of redo information, all written to the log file. If all available space in the log files is used up, a sharp checkpoint occurs, causing a temporary reduction in throughput. This situation can happen even though `innodb_max_dirty_pages_pct` is not reached.

InnoDB uses a heuristic-based algorithm to avoid such a scenario, by measuring the number of dirty pages in the buffer pool and the rate at which redo is being generated. Based on these numbers, InnoDB decides how many dirty pages to flush from the buffer pool each second. This self-adapting algorithm is able to deal with sudden changes in the workload.

Internal benchmarking has also shown that this algorithm not only maintains throughput over time, but can also improve overall throughput significantly.

Because adaptive flushing is a new feature that can significantly affect the I/O pattern of a workload, a new configuration parameter lets you turn off this feature. The default value of the boolean parameter `innodb_adaptive_flushing` is `TRUE`, enabling the new algorithm. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

For more information about InnoDB I/O performance, see [Section 7.5.7, “Optimizing InnoDB Disk I/O”](#).

### 13.4.7.13. Using the PAUSE Instruction in InnoDB Spin Loops

Synchronization inside InnoDB frequently involves the use of [spin](#) loops: while waiting, InnoDB executes a tight loop of instructions repeatedly to avoid having the InnoDB [process](#) and [threads](#) be rescheduled by the operating system. If the spin loops are executed too quickly, system resources are wasted, imposing a performance penalty on transaction throughput. Most modern processors implement the [PAUSE](#) instruction for use in spin loops, so the processor can be more efficient.

InnoDB uses a [PAUSE](#) instruction in its spin loops on all platforms where such an instruction is available. This technique increases overall performance with CPU-bound workloads, and has the added benefit of minimizing power consumption during the execution of the spin loops.

You do not have to do anything to take advantage of this performance improvement.

For performance considerations for InnoDB locking operations, see [Section 7.10, “Optimizing Locking Operations”](#).

### 13.4.7.14. Control of Spin Lock Polling

Many InnoDB [mutexes](#) and [rw-locks](#) are reserved for a short time. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a while before sleeping. If the mutex or rw-lock becomes available during this polling period, the thread can continue immediately, in the same time slice. However, too-frequent polling by multiple threads of a shared object can cause “cache ping pong”, different processors invalidating portions of each others' cache. InnoDB minimizes this issue by waiting a random time between subsequent polls. The delay is implemented as a busy loop.

You can control the maximum delay between testing a mutex or rw-lock using the parameter `innodb_spin_wait_delay`. The duration of the delay loop depends on the C compiler and the target processor. (In the 100MHz Pentium era, the unit of delay was one microsecond.) On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting `innodb_spin_wait_delay=0`. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The default value of `innodb_spin_wait_delay` is 6. The spin wait delay is a dynamic global parameter that you can specify in the MySQL option file (`my.cnf` or `my.ini`) or change at runtime with the command `SET GLOBAL innodb_spin_wait_delay=delay`, where `delay` is the desired maximum delay. Changing the setting requires the [SUPER](#) privilege.

For performance considerations for InnoDB locking operations, see [Section 7.10, “Optimizing Locking Operations”](#).

### 13.4.7.15. Making Buffer Pool Scan Resistant

Rather than using a strictly [LRU](#) algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the [buffer pool](#) and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as [read-ahead](#) and [full table scans](#) bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the list representing the buffer pool, of the LRU list. All newly read pages are inserted at a location that by default is  $3/8$  from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus pages that are never accessed never make it to the front portion of the LRU list, and “age out” sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the InnoDB buffer pool and the specifics of its LRU replacement algorithm, see [Section 7.9.1, “The InnoDB Buffer Pool”](#).

You can control the insertion point in the LRU list, and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of  $3/8$ . The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 0, corresponding to the original behavior of moving a page to the most-recently used end of the buffer

pool list when it is first accessed in the buffer pool. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both the new parameters `innodb_old_blocks_pct` and `innodb_old_blocks_time` are dynamic, global and can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` command. Changing the setting requires the `SUPER` privilege.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports additional statistics. The `BUFFER POOL AND MEMORY` section now looks like:

```
Total memory allocated 1107296256; in additional pool allocated 0
Dictionary memory allocated 80360
Buffer pool size 65535
Free buffers 0
Database pages 63920
Old database pages 23600
Modified db pages 34969
Pending reads 32
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 414946, not young 2930673
1274.75 youngs/s, 16521.90 non-youngs/s
Pages read 486005, created 3178, written 160585
2132.37 reads/s, 3.40 creates/s, 323.74 writes/s
Buffer pool hit rate 950 / 1000, young-making rate 30 / 1000 not 392 / 1000
Pages read ahead 1510.10/s, evicted without access 0.00/s
LRU len: 63920, unzip_LRU len: 0
I/O sum[43690]:cur[221], unzip sum[0]:cur[0]
```

- `Old database pages` is the number of pages in the “old” segment of the LRU list.
- `Pages made young` and `not young` is the total number of “old” pages that have been made young or not respectively.
- `youngs/s` and `non-young/s` is the rate at which page accesses to the “old” pages have resulted in making such pages young or otherwise respectively since the last invocation of the command.
- `young-making rate` and `not` provides the same rate but in terms of overall buffer pool accesses instead of accesses just to the “old” pages.

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

For more information about the InnoDB buffer pool, see [Section 7.9.1, “The InnoDB Buffer Pool”](#).

### 13.4.7.16. Improvements to Crash Recovery Performance

A number of optimizations speed up certain steps of the [recovery](#) that happens on the next startup after a crash. In particular, scanning the [redo log](#) and applying the redo log are faster than in MySQL 5.1 and earlier, due to improved algorithms for memory management. You do not need to take any actions to take advantage of this performance enhancement. If you kept the size of your redo log files artificially low because recovery took a long time, you can consider increasing the file size.

For more information about InnoDB recovery, see [Section 13.3.7.1, “The InnoDB Recovery Process”](#).

### 13.4.7.17. Integration with MySQL PERFORMANCE\_SCHEMA

Starting with InnoDB 1.1 with MySQL 5.5, you can profile certain internal InnoDB operations using the MySQL [Performance Schema feature](#). This type of tuning is primarily for expert users, those who push the limits of MySQL performance, read the MySQL source code, and evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be running MySQL 5.5 or higher. You must build the database server from source, enabling the Performance Schema feature by building with the `--with-perfschema` option. Since the Performance Schema feature introduces some performance overhead, you should use it on a test or development system rather than on a production system.
- You must be running InnoDB 1.1 or higher.
- You must be generally familiar with how to use the [Performance Schema feature](#), for example to query tables in the `performance_schema` database.
- Examine the following kinds of InnoDB objects by querying the appropriate `performance_schema` tables. The items associated with InnoDB all contain the substring `innodb` in the `NAME` column.

For the definitions of the `*_instances` tables, see [Section 20.7.2, “Performance Schema Instance Tables”](#). For the definitions of the `*_summary_*` tables, see [Section 20.7.4, “Performance Schema Summary Tables”](#). For the definition of the `thread` table, see [Section 20.7.5, “Performance Schema Miscellaneous Tables”](#). For the definition of the `*_current_*` and `*_history_*` tables, see [Section 20.7.3, “Performance Schema Wait Event Tables”](#).

- [Mutexes](#) in the `mutex_instances` table. (Mutexes and RW-locks related to the InnoDB buffer pool are not included in this coverage; the same applies to the output of the `SHOW ENGINE INNODB MUTEX` command.)
- [RW-locks](#) in the `rwlock_instances` table.
- RW-locks in the `rwlock_instances` table.
- File I/O operations in the `file_instances`, `file_summary_by_event_name`, and `file_summary_by_instance` tables.
- [Threads](#) in the `PROCESSLIST` table.
- During performance testing, examine the performance data in the `events_waits_current` and `events_waits_history_long` tables. If you are interested especially in InnoDB-related objects, use the clause `where name like "%innodb%"` to see just those entries; otherwise, examine the performance statistics for the overall MySQL server.
- You must be running MySQL 5.5, with the Performance Schema enabled by building with the `--with-perfschema` build option.

For more information about the MySQL Performance Schema, see [Chapter 20, MySQL Performance Schema](#).

### 13.4.7.18. Improvements to Performance from Multiple Buffer Pools

This performance enhancement is primarily useful for people with a large [buffer pool](#) size, typically in the multi-gigabyte range. To take advantage of this speedup, you must set the new `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the InnoDB buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. Starting in InnoDB 1.1 and MySQL 5.5, you can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable this feature, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option only takes effect when you set the `innodb_buffer_pool_size` to a size of 1 gigabyte or more. The total size you specify is divided up among all the buffer pools. We recommend specifying a combination of `in-`

`nodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1 gigabyte.

For more information about the InnoDB buffer pool, see [Section 7.9.1, “The InnoDB Buffer Pool”](#).

### 13.4.7.19. Better Scalability with Multiple Rollback Segments

Starting in InnoDB 1.1 with MySQL 5.5, the limit on concurrent [transactions](#) is greatly expanded, removing a bottleneck with the InnoDB [rollback segment](#) that affected high-capacity systems. The limit applies to concurrent transactions that change any data; read-only transactions do not count against that maximum.

The single rollback segment is now divided into 128 segments, each of which can support up to 1023 transactions that perform writes, for a total of approximately 128K concurrent transactions. The original transaction limit was 1023.

Each transaction is assigned to one of the rollback segments, and remains tied to that rollback segment for the duration. This enhancement improves both scalability (higher number of concurrent transactions) and performance (less contention when different transactions access the rollback segments).

To take advantage of this feature, you do not need to create any new database or tables, or reconfigure anything. You must do a [slow shutdown](#) before upgrading from MySQL 5.1 or earlier, or some time afterward. InnoDB makes the required changes inside the [system tablespace](#) automatically, the first time you restart after performing a slow shutdown.

For more information about performance of InnoDB under high transactional load, see [Section 7.5.2, “Optimizing InnoDB Transaction Management”](#).

### 13.4.7.20. Better Scalability with Improved Purge Scheduling

Starting in InnoDB 1.1 with MySQL 5.5, the [purge](#) operations (a type of garbage collection) that InnoDB performs automatically can be done in a separate thread, rather than as part of the [master thread](#). This change improves scalability, because the main database operations run independently from maintenance work happening in the background.

To enable this feature, set the configuration option `innodb_purge_threads=1`, as opposed to the default of 0, which combines the purge operation into the master thread.

You might not notice a significant speedup, because the purge thread might encounter new types of contention; the single purge thread really lays the groundwork for further tuning and possibly multiple purge threads in the future. There is another new configuration option, `innodb_purge_batch_size` with a default of 20 and maximum of 5000. This option is mainly intended for experimentation and tuning of purge operations, and should not be interesting to typical users.

For more information about InnoDB I/O performance, see [Section 7.5.7, “Optimizing InnoDB Disk I/O”](#).

### 13.4.7.21. Improved Log Sys Mutex

This is another performance improvement that comes for free, with no user action or configuration needed. The details here are intended for performance experts who delve into the InnoDB source code, or interpret reports with keywords such as “mutex” and “log\_sys”.

The [mutex](#) known as the log sys mutex has historically done double duty, controlling access to internal data structures related to log records and the [LSN](#), as well as pages in the [buffer pool](#) that are changed when a [mini-transaction](#) is committed. Starting in InnoDB 1.1 with MySQL 5.5, these two kinds of operations are protected by separate mutexes, with a new `log_buf` mutex controlling writes to buffer pool pages due to mini-transactions.

For performance considerations for InnoDB locking operations, see [Section 7.10, “Optimizing Locking Operations”](#).

### 13.4.7.22. Separate Flush List Mutex

Starting with InnoDB 1.1 with MySQL 5.5, concurrent access to the [buffer pool](#) is faster. Operations involving the [flush list](#), a data structure related to the buffer pool, are now controlled by a separate [mutex](#) and do not block access to the buffer pool. You do not need to configure anything to take advantage of this speedup; it is fully automatic.

For more information about the InnoDB buffer pool, see [Section 7.9.1, “The InnoDB Buffer Pool”](#).

## 13.4.8. Changes for Flexibility, Ease of Use and Reliability

This chapter describes several recently added InnoDB features that offer new flexibility and improve ease of use, reliability and performance. The [Barracuda](#) file format improves efficiency for storing large variable-length columns, and enables table compression. Configuration options that once were unchangeable after startup, are now flexible and can be changed dynamically. Some improve-

ments are automatic, such as faster and more efficient `TRUNCATE TABLE`. Others allow you the flexibility to control InnoDB behavior; for example, you can control whether certain problems cause errors or just warnings. And informational messages and error reporting continue to be made more user-friendly.

### 13.4.8.1. The Barracuda File Format

InnoDB has started using named file formats to improve compatibility in upgrade and downgrade situations, or heterogeneous systems running different levels of MySQL. Many important InnoDB features, such as table compression and the `DYNAMIC` row format for more efficient BLOB storage, require creating tables in the `Barracuda` file format. The original file format, which previously didn't have a name, is known now as `Antelope`.

To create new tables that take advantage of the Barracuda features, enable that file format using the configuration parameter `innodb_file_format`. The value of this parameter determines whether a newly created table or index can use compression or the new `DYNAMIC` row format.

To preclude the use of new features that would make your database inaccessible to the built-in InnoDB in MySQL 5.1 and prior releases, omit `innodb_file_format` or set it to `Antelope`.

You can set the value of `innodb_file_format` on the command line when you start `mysqld`, or in the option file `my.cnf` (Unix operating systems) or `my.ini` (Windows). You can also change it dynamically with the `SET GLOBAL` statement.

For more information about managing file formats, see [Section 13.4.4, “InnoDB File-Format Management”](#).

### 13.4.8.2. Dynamic Control of System Configuration Parameters

In MySQL 5.5 and higher, you can change certain system configuration parameters without shutting down and restarting the server, as was necessary in MySQL 5.1 and lower. This increases uptime, and makes it easier to test and prototype new SQL and application code. The following sections explain these parameters.

#### 13.4.8.2.1. Dynamically Changing `innodb_file_per_table`

Since MySQL version 4.1, InnoDB has provided two alternatives for how tables are stored on disk. You can create a new table and its indexes in the shared `system tablespace`, physically stored in the `ibdata files`. Or, you can store a new table and its indexes in a separate tablespace (a `.ibd file`). The storage layout for each InnoDB table is determined by the configuration parameter `innodb_file_per_table` at the time the table is created.

In MySQL 5.5 and higher, the configuration parameter `innodb_file_per_table` is dynamic, and can be set `ON` or `OFF` using the `SET GLOBAL`. Previously, the only way to set this parameter was in the MySQL option file (`my.cnf` or `my.ini`), and changing it required shutting down and restarting the server.

The default setting is `OFF`, so new tables and indexes are created in the system tablespace. Dynamically changing the value of this parameter requires the `SUPER` privilege and immediately affects the operation of all connections.

Tables created when `innodb_file_per_table` is enabled can use the `Barracuda` file format, and `TRUNCATE` returns the disk space for those tables to the operating system. The Barracuda file format in turn enables features such as table compression and the `DYNAMIC` row format. Tables created when `innodb_file_per_table` is off cannot use these features. To take advantage of those features for an existing table, you can turn on the file-per-table setting and run `ALTER TABLE t ENGINE=INNODB` for that table.

When you redefine the primary key for an InnoDB table, the table is re-created using the current settings for `innodb_file_per_table` and `innodb_file_format`. This behavior does not apply when adding or dropping InnoDB secondary indexes, as explained in [Section 13.4.2, “Fast Index Creation in the InnoDB Storage Engine”](#). When a secondary index is created without rebuilding the table, the index is stored in the same file as the table data, regardless of the current `innodb_file_per_table` setting.

#### 13.4.8.2.2. Dynamically Changing `innodb_stats_on_metadata`

In MySQL 5.5 and higher, you can change the setting of `innodb_stats_on_metadata` dynamically at runtime, to control whether or not InnoDB performs statistics gathering when metadata statements are executed. To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where `mode` is either `ON` or `OFF` (or `1` or `0`). Changing this setting requires the `SUPER` privilege and immediately affects the operation of all connections.

This setting is related to the feature described in [Section 13.4.8.5, “Controlling Optimizer Statistics Estimation”](#).

#### 13.4.8.2.3. Dynamically Changing `innodb_lock_wait_timeout`

The length of time a transaction waits for a resource, before giving up and rolling back the statement, is determined by the value of the configuration parameter `innodb_lock_wait_timeout`. (In MySQL 5.0.12 and earlier, the entire transaction was rolled back, not just the statement.) Your application can try the statement again (usually after waiting for a while), or roll back the entire transaction and restart.

The error returned when the timeout period is exceeded is:

```
ERROR HY000: Lock wait timeout exceeded; try restarting transaction
```

In MySQL 5.5 and higher, the configuration parameter `innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

In MySQL 5.1 and earlier, the only way to set this parameter was in the MySQL option file (`my.cnf` or `my.ini`), and changing it required shutting down and restarting the server.

#### 13.4.8.2.4. Dynamically Changing `innodb_adaptive_hash_index`

As described in [Section 13.4.7.5, “Controlling Adaptive Hash Indexing”](#), it may be desirable, depending on your workload, to dynamically enable or disable the `adaptive hash indexing` scheme InnoDB uses to improve query performance.

The start-up option `innodb_adaptive_hash_index` allows the adaptive hash index to be disabled. It is enabled by default. You can modify this parameter through the `SET GLOBAL` statement, without restarting the server. Changing the setting requires the `SUPER` privilege.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

#### 13.4.8.3. `TRUNCATE TABLE` Reclaims Space

When you `truncate` a table that is stored in a `.ibd` file of its own (because `innodb_file_per_table` was enabled when the table was created), and if the table is not referenced in a `FOREIGN KEY` constraint, the table is dropped and re-created in a new `.ibd` file. This operation is much faster than deleting the rows one by one. The operating system can reuse the disk space, in contrast to tables within the InnoDB `system tablespace`, where only InnoDB can use the space after they are truncated. [Physical backups](#) can also be smaller, without big blocks of unused space in the middle of the system tablespace.

Previous versions of InnoDB would re-use the existing `.ibd` file, thus releasing the space only to InnoDB for storage management, but not to the operating system. Note that when the table is truncated, the count of rows affected by the `TRUNCATE TABLE` statement is an arbitrary number.

##### Note

If there is a referential constraint between two columns in the same table, that table can still be truncated using this fast technique.

If there are referential constraints between the table being truncated and other tables, the truncate operation fails. This is a change to the previous behavior, which would transform the `TRUNCATE` operation to a `DELETE` operation that removed all the rows and triggered `ON DELETE` operations on [child tables](#).

#### 13.4.8.4. InnoDB Strict Mode

To guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements, InnoDB provides a `strict mode` of operations. In this mode, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values. Since strict mode is relatively new, some statements that execute without errors with earlier versions of MySQL might generate errors unless you disable strict mode.

The setting of InnoDB strict mode affects the handling of syntax errors on the `CREATE TABLE`, `ALTER TABLE` and `CREATE INDEX` statements. The strict mode also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

We recommend running in strict mode when using the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses on `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. Without strict mode, InnoDB ignores conflicting clauses and creates the table or index, with only a warning in the message log. The resulting table might have different behavior than you intended, such as having no compression when you tried to create a compressed table. When InnoDB strict mode is on, such problems generate an immediate error and the table or index is not created, avoiding a troubleshooting session later.

InnoDB strict mode is set with the configuration parameter `innodb_strict_mode`, which can be specified as `on` or `off`. You can set the value on the command line when you start `mysqld`, or in the configuration file `my.cnf` or `my.ini`. You can also enable or disable InnoDB strict mode at run time with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

### 13.4.8.5. Controlling Optimizer Statistics Estimation

The MySQL query optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative `selectivity` of the index. Certain operations cause InnoDB to sample random pages from each index on a table to estimate the `cardinality` of the index. (This technique is known as `random dives`.) These operations include the `ANALYZE TABLE` statement, the `SHOW TABLE STATUS` statement, and accessing the table for the first time after a restart.

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can now change the number of sampled pages using the parameter `innodb_stats_sample_pages`. Previously, the number of sampled pages was always 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in `joins`. Unnecessary `full table scans` for such tables can be a substantial performance issue.

You can set the global parameter `innodb_stats_sample_pages`, at run time. The default value for this parameter is 8, preserving the same behavior as in past releases.

#### Note

The value of `innodb_stats_sample_pages` affects the index sampling for *all* tables and indexes. There are the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in very inaccurate estimates of cardinality.
- Increasing the `innodb_stats_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a big slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.
- The optimizer might choose very different query plans based on different estimates of index selectivity.

To disable the cardinality estimation for metadata statements such as `SHOW TABLE STATUS`, execute the statement `SET GLOBAL innodb_stats_on_metadata=OFF` (or 0). The ability to set this option dynamically is also relatively new.

All InnoDB tables are opened, and the statistics are re-estimated for all associated indexes, when the `mysql` client starts if the auto-rehash setting is set on (the default). To improve the start up time of the `mysql` client, you can turn auto-rehash off. The auto-rehash feature enables automatic name completion of database, table, and column names for interactive users.

Whatever value of `innodb_stats_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again. The more accurate statistics calculated by `ANALYZE` running with a high value of `innodb_stats_sample_pages` can be wiped away later.

Although it is not possible to specify the sample size on a per-table basis, smaller tables generally require fewer index samples than larger tables do. If your database has many large tables, consider using a higher value for `innodb_stats_sample_pages` than if you have mostly smaller tables.

### 13.4.8.6. Better Error Handling when Dropping Indexes

For optimal performance with DML statements, InnoDB requires an index to exist on `foreign key` columns, so that `UPDATE` and `DELETE` operations on a `parent table` can easily check whether corresponding rows exist in the `child table`. MySQL creates or drops such indexes automatically when needed, as a side-effect of `CREATE TABLE`, `CREATE INDEX`, and `ALTER TABLE` statements.

When you drop an index, InnoDB checks whether the index is not used for checking a foreign key constraint. It is still OK to drop the index if there is another index that can be used to enforce the same constraint. InnoDB prevents you from dropping the last index that can enforce a particular referential constraint.

The message that reports this error condition is:

```
ERROR 1553 (HY000): Cannot drop index 'fooIdx':
needed in a foreign key constraint
```

This message is friendlier than the earlier message it replaces:

```
ERROR 1025 (HY000): Error on rename of './db2/#sql-18eb_3'
to './db2/foo'(errno: 150)
```

A similar change in error reporting applies to an attempt to drop the primary key index. For tables without an explicit `PRIMARY KEY`, InnoDB creates an implicit `clustered index` using the first columns of the table that are declared `UNIQUE` and `NOT NULL`. When you drop such an index, InnoDB automatically copies the table and rebuilds the index using a different `UNIQUE NOT NULL` group of columns or a system-generated key. Since this operation changes the primary key, it uses the slow method of copying the table and re-creating the index, rather than the Fast Index Creation technique from [Section 13.4.2.3, “Implementation Details of Fast Index Creation”](#).

Previously, an attempt to drop an implicit clustered index (the first `UNIQUE NOT NULL` index) failed if the table did not contain a `PRIMARY KEY`:

```
ERROR 42000: This table type requires a primary key
```

### 13.4.8.7. More Compact Output of `SHOW ENGINE INNODB MUTEX`

The statement `SHOW ENGINE INNODB MUTEX` displays information about InnoDB `mutexes` and `rw-locks`. Although this information is useful for tuning on multi-core systems, the amount of output can be overwhelming on systems with a big `buffer pool`. There is one mutex and one rw-lock in each 16K buffer pool block, and there are 65,536 blocks per gigabyte. It is unlikely that a single block mutex or rw-lock from the buffer pool could become a performance bottleneck.

`SHOW ENGINE INNODB MUTEX` now skips the mutexes and rw-locks of buffer pool blocks. It also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level `wait`.

### 13.4.8.8. More Read-Ahead Statistics

As described in [Section 13.4.7.7, “Changes in the Read-Ahead Algorithm”](#), a read-ahead request is an asynchronous I/O request issued in anticipation that a page will be used in the near future. Knowing how many pages are read through this read-ahead mechanism, and how many of them are evicted from the buffer pool without ever being accessed, can be useful to help fine-tune the parameter `innodb_read_ahead_threshold`.

`SHOW ENGINE INNODB STATUS` output displays the global status variables `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted`. These variables indicate the number of pages brought into the `buffer pool` by read-ahead requests, and the number of such pages `evicted` from the buffer pool without ever being accessed respectively. These counters provide global values since the last server restart.

`SHOW ENGINE INNODB INNODB STATUS` also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB INNODB STATUS` and are displayed in the `BUFFER POOL AND MEMORY` section of the output.

Since the InnoDB read-ahead mechanism has been simplified to remove random read-ahead, the status variables `Innodb_buffer_pool_read_ahead_rnd` and `Innodb_buffer_pool_read_ahead_seq` are no longer part of the `SHOW ENGINE INNODB STATUS` output.

## 13.4.9. Installing the InnoDB Storage Engine

When you use the InnoDB storage engine 1.1 and above, with MySQL 5.5 and above, you do not need to do anything special to install: everything comes configured as part of the MySQL source and binary distributions. This is a change from earlier releases of the InnoDB Plugin, where you were required to match up MySQL and InnoDB version numbers and update your build and configuration processes.

The InnoDB storage engine is included in the MySQL distribution, starting from MySQL 5.1.38. From MySQL 5.1.46 and up, this is the only download location for the InnoDB storage engine; it is not available from the InnoDB web site.

If you used any scripts or configuration files with the earlier InnoDB storage engine from the InnoDB web site, be aware that the file-name of the shared library as supplied by MySQL is `ha_innodb_plugin.so` or `ha_innodb_plugin.dll`, as opposed to `ha_innodb.so` or `ha_innodb.dll` in the older Plugin downloaded from the InnoDB web site. You might need to change the applicable file names in your startup or configuration scripts.

Because the InnoDB storage engine has now replaced the built-in InnoDB, you no longer need to specify options like `-ignore-builtin-innodb` and `--plugin-load` during startup.

To take best advantage of current InnoDB features, we recommend specifying the following options in your configuration file:

```
innodb_file_per_table=1
innodb_file_format=barracuda
innodb_strict_mode=1
```

For information about these new features, see [Section 13.4.8.2.1, “Dynamically Changing `innodb\_file\_per\_table`”](#), [Section 13.4.4, “InnoDB File-Format Management”](#), and [Section 13.4.8.4, “InnoDB Strict Mode”](#). You might need to continue to use the previous values for these parameters in some replication and similar configurations involving both new and older versions of MySQL.

## 13.4.10. Upgrading the InnoDB Storage Engine

Prior to MySQL 5.5, some upgrade scenarios involved upgrading the separate instance of InnoDB known as the InnoDB Plugin. In MySQL 5.5 and higher, the features of the InnoDB Plugin have been folded back into built-in InnoDB, so the upgrade procedure for InnoDB is the same as the one for the MySQL server. For details, see [Section 2.11.1, “Upgrading MySQL”](#).

## 13.4.11. Downgrading the InnoDB Storage Engine

### 13.4.11.1. Overview

Prior to MySQL 5.5, some downgrade scenarios involved switching the separate instance of InnoDB known as the InnoDB Plugin back to the built-in InnoDB storage engine. In MySQL 5.5 and higher, the features of the InnoDB Plugin have been folded back into built-in InnoDB, so the downgrade procedure for InnoDB is the same as the one for the MySQL server. For details, see [Section 2.11.2, “Downgrading MySQL”](#).

## 13.4.12. InnoDB Storage Engine Change History

### 13.4.12.1. Changes in InnoDB Storage Engine 1.x

Since InnoDB 1.1 is tightly integrated with MySQL 5.5, for changes after the initial InnoDB 1.1 release, see the MySQL 5.5 Reference Manual, [Section D.1, “Changes in Release 5.5.x \(Production\)”](#).

### 13.4.12.2. Changes in InnoDB Storage Engine 1.1 (April 13, 2010)

For an overview of the changes, see [this introduction article for MySQL 5.5 with InnoDB 1.1](#). The following is a condensed version of the change log.

Fix for bug [#52580](#): Crash in `ha_innobase::open` on executing INSERT with concurrent ALTER TABLE.

Change in MySQL bug [#51557](#) releases the mutex `LOCK_open` before `ha_innobase::open()`, causing racing condition for index translation table creation. Fix it by adding `dict_sys` mutex for the operation.

Add support for multiple buffer pools.

Fix Bug [#26590](#): MySQL does not allow more than 1023 open transactions. Create additional rollback segments on startup. Reduce the upper limit of total rollback segments from 256 to 128. This is because we can't use the sign bit. It has not caused problems in the past because we only created one segment. InnoDB has always had the capability to use the additional rollback segments, therefore this patch is backward compatible. The only requirement to maintain backward compatibility has been to ensure that the additional segments are created after the double write buffer. This is to avoid breaking assumptions in the existing code.

Implement Performance Schema in InnoDB. Objects in four different modules in InnoDB have been performance instrumented, these modules are: mutexes, rwlocks, file I/O, and threads. We mostly preserved the existing APIs, but APIs would point to instrumented

function wrappers if performance schema is defined. There are 4 different defines that controls the instrumentation of each module. The feature is off by default, and will be compiled in with special build option, and require configure option to turn it on when server boots.

Implement the `buf_pool_watch` for `DeleteBuffering` in the page hash table. This serves two purposes. It allows multiple watches to be set at the same time (by multiple purge threads) and it removes a race condition when the read of a block completes about the time the buffer pool watch is being set.

Introduce a new mutex to protect `flush_list`. Redesign `mtr_commit()` in a way that `log_sys` mutex is not held while all `mtr_memos` are popped and is released just after the modified blocks are inserted into the `flush_list`. This should reduce contention on `log_sys` mutex.

Implement the global variable `innodb_change_buffering`, with the following values:

- `none`: buffer nothing
- `inserts`: buffer inserts (like InnoDB so far)
- `deletes`: buffer delete-marks
- `changes`: buffer inserts and delete-marks
- `purges`: buffer delete-marks and deletes
- `all`: buffer all operations (insert, delete-mark, delete)

The default is `all`. All values except `none` and `inserts` will make InnoDB write new-format records to the insert buffer, even for inserts.

Provide support for native AIO on Linux.

### 13.4.12.3. Changes in InnoDB Plugin 1.0.x

The InnoDB 1.0.x releases that accompany MySQL 5.1 have their own change history. Changes up to InnoDB 1.0.8 are listed at <http://dev.mysql.com/doc/innodb-plugin/1.0/en/innodb-changes.html>. Changes from InnoDB 1.0.9 and up are listed in [Changes in Release 5.1.x \(Production\)](#), incorporated into the main MySQL change log.

## 13.4.13. Third-Party Software

Oracle acknowledges that certain Third Party and Open Source software has been used to develop or is incorporated in the InnoDB storage engine. This appendix includes required third-party license information.

### 13.4.13.1. Performance Patches from Google

Oracle gratefully acknowledges the following contributions from Google, Inc. to improve InnoDB performance:

- Replacing InnoDB's use of Pthreads mutexes with calls to GCC atomic builtins, as discussed in [Section 13.4.7.2, "Faster Locking for Improved Scalability"](#). This change means that InnoDB mutex and rw-lock operations take less CPU time, and improves throughput on those platforms where the atomic operations are available.
- Controlling master thread I/O rate, as discussed in [Section 13.4.7.11, "Controlling the Master Thread I/O Rate"](#). The master thread in InnoDB is a thread that performs various tasks in the background. Historically, InnoDB has used a hard coded value as the total I/O capacity of the server. With this change, user can control the number of I/O operations that can be performed per second based on their own workload.

Changes from the Google contributions were incorporated in the following source code files: `btr0cur.c`, `btr0sea.c`, `buf0buf.c`, `buf0buf.ic`, `ha_innodb.cc`, `log0log.c`, `log0log.h`, `os0sync.h`, `row0sel.c`, `srv0srv.c`, `srv0srv.h`, `srv0start.c`, `sync0arr.c`, `sync0rw.c`, `sync0rw.h`, `sync0rw.ic`, `sync0sync.c`, `sync0sync.h`, `sync0sync.ic`, and `univ.i`.

These contributions are incorporated subject to the conditions contained in the file `COPYING.Google`, which are reproduced here.

POSSIBILITY OF SUCH DAMAGE.

```

### 13.4.13.2. Multiple Background I/O Threads Patch from Percona

Oracle gratefully acknowledges the contribution of Percona, Inc. to improve InnoDB performance by implementing configurable background threads, as discussed in [Section 13.4.7.8, “Multiple Background I/O Threads”](#). InnoDB uses background threads to service various types of I/O requests. The change provides another way to make InnoDB more scalable on high end systems.

Changes from the Percona, Inc. contribution were incorporated in the following source code files: [ha\\_innodb.cc](#), [os0file.c](#), [os0file.h](#), [srv0srv.c](#), [srv0srv.h](#), and [srv0start.c](#).

This contribution is incorporated subject to the conditions contained in the file [COPYING.Percona](#), which are reproduced here.

### 13.4.13.3. Performance Patches from Sun Microsystems

Oracle gratefully acknowledges the following contributions from Sun Microsystems, Inc. to improve InnoDB performance:

- Introducing the PAUSE instruction inside spin loops, as discussed in [Section 13.4.7.13, “Using the PAUSE Instruction in InnoDB Spin Loops”](#). This change increases performance in high concurrency, CPU-bound workloads.
- Enabling inlining of functions and prefetch with Sun Studio.

Changes from the Sun Microsystems, Inc. contribution were incorporated in the following source code files: [univ.i](#), [ut0ut.c](#), and [ut0ut.h](#).

This contribution is incorporated subject to the conditions contained in the file [COPYING.Sun\\_Microsystems](#), which are repro-

duced here.

## 13.4.14. List of Parameters Changed in InnoDB 1.1 and InnoDB Plugin 1.0

### 13.4.14.1. New Parameters

Throughout the course of development, InnoDB 1.1 and its predecessor the InnoDB Plugin introduced new configuration parameters. The following table summarizes those parameters:

**Table 13.8. InnoDB 1.1 New Parameter Summary**

Name	Cmd-Line	Option File	System Var	Scope	Dynamic	Default
<code>innodb_adaptive_flushing</code>	YES	YES	YES	GLOBAL	YES	TRUE
<code>innodb_buffer_pool_instances</code>	YES	YES	YES	GLOBAL	YES	TRUE
<code>innodb_change_buffering</code>	YES	YES	YES	GLOBAL	YES	<code>inserts</code>
<code>innodb_file_format</code>	YES	YES	YES	GLOBAL	YES	Antelope
<code>innodb_file_format_check</code>	YES	YES	YES	GLOBAL	NO	1
<code>innodb_file_format_max</code>	YES	YES	YES	GLOBAL	YES	Antelope for a new database; Barracuda if any tables using that file format exist in the database
<code>innodb_io_capacity</code>	YES	YES	YES	GLOBAL	YES	200
<code>innodb_old_blocks_pct</code>	YES	YES	YES	GLOBAL	YES	37
<code>innodb_old_blocks_time</code>	YES	YES	YES	GLOBAL	YES	0
<code>innodb_purge_batch_size</code>	YES	YES	YES	GLOBAL	YES	0
<code>innodb_purge_threads</code>	YES	YES	YES	GLOBAL	YES	0
<code>innodb_read_ahead_threshold</code>	YES	YES	YES	GLOBAL	YES	56
<code>innodb_read_io_threads</code>	YES	YES	YES	GLOBAL	NO	4
<code>innodb_spin_wait_delay</code>	YES	YES	YES	GLOBAL	YES	6
<code>innodb_stats_sample_pages</code>	YES	YES	YES	GLOBAL	YES	8
<code>innodb_strict_mode</code>	YES	YES	YES	GLOBAL   SESSION	YES	FALSE

Name	Cmd-Line	Option File	System Var	Scope	Dynamic	Default
<code>innodb_use_native_aio</code>	YES	YES	YES	GLOBAL	NO	TRUE
<code>innodb_use_sys_malloc</code>	YES	YES	YES	GLOBAL	NO	TRUE
<code>innodb_write_io_threads</code>	YES	YES	YES	GLOBAL	NO	4

- `innodb_adaptive_flushing`

Whether InnoDB uses a new algorithm to estimate the required rate of flushing. The default value is `TRUE`. This parameter was added in InnoDB storage engine 1.0.4. See [Section 13.4.7.12, “Controlling the Flushing Rate of Dirty Pages”](#) for more information.

- `innodb_change_buffering`

Whether InnoDB performs insert buffering. The default value is `"inserts"` (buffer insert operations). This parameter was added in InnoDB storage engine 1.0.3. See [Section 13.4.7.4, “Controlling InnoDB Change Buffering”](#) for more information.

- `innodb_file_format`

The default file format for new InnoDB tables. The default is Antelope. To enable support for table compression, change it to Baracuda. This parameter was added in InnoDB storage engine 1.0.1. See [Section 13.4.4.1, “Enabling File Formats”](#) for more information.

- `innodb_file_format_check` and `innodb_file_format_max`

Controls whether InnoDB performs file format compatibility checking when opening a database. The default value is `innodb-file-format-check=1`, with `innodb_file_format_max` set to the highest format that is used in the database (either Baracuda or Antelope). See [Section 13.4.4.2.1, “Compatibility Check When InnoDB Is Started”](#) for more information.

- `innodb_io_capacity`

The number of I/O operations that can be performed per second. The allowable value range is any number 100 or greater, and the default value is 200. This parameter was added in InnoDB storage engine 1.0.4. To reproduce the earlier behavior, use a value of 100. See [Section 13.4.7.11, “Controlling the Master Thread I/O Rate”](#) for more information.

- `innodb_old_blocks_pct`

Controls the desired percentage of “old” blocks in the LRU list of the buffer pool. The default value is 37 and the allowable value range is 5 to 95. This parameter was added in InnoDB storage engine 1.0.5. See [Section 13.4.7.15, “Making Buffer Pool Scan Resistant”](#) for more information.

- `innodb_old_blocks_time`

The time in milliseconds since the first access to a block during which it can be accessed again without being made “young”. The default value is 0 which means that blocks are moved to the “young” end of the LRU list at the first access. This parameter was added in InnoDB storage engine 1.0.5. See [Section 13.4.7.15, “Making Buffer Pool Scan Resistant”](#) for more information.

- `innodb_read_ahead_threshold`

Control the sensitivity of the linear read ahead. The allowable value range is 0 to 64 and the default value is 56. This parameter was added in InnoDB storage engine 1.0.4. See [Section 13.4.7.7, “Changes in the Read-Ahead Algorithm”](#) for more information.

- `innodb_read_io_threads`

The number of background I/O threads used for reads. The allowable value range is 1 to 64 and the default value is 4. This parameter was added in InnoDB storage engine 1.0.4. See [Section 13.4.7.8, “Multiple Background I/O Threads”](#) for more information.

- `innodb_spin_wait_delay`

Maximum delay between polling for a spin lock. The allowable value range is 0 (meaning unlimited) or positive integers and the default value is 6. This parameter was added in InnoDB storage engine 1.0.4. See [Section 13.4.7.14, “Control of Spin Lock Polling”](#) for more information.

- `innodb_stats_sample_pages`

The number of index pages to sample when calculating statistics. The allowable value range is `1-unlimited` and the default value is `8`. This parameter was added in InnoDB storage engine 1.0.2. See [Section 13.4.8.5, “Controlling Optimizer Statistics Estimation”](#) for more information.

- `innodb_strict_mode`

Whether InnoDB raises error conditions in certain cases, rather than issuing a warning. This parameter was added in InnoDB storage engine 1.0.2. See [Section 13.4.8.4, “InnoDB Strict Mode”](#) for more information.

- `innodb_use_sys_malloc`

Whether InnoDB uses its own memory allocator or an allocator of the operating system. The default value is `ON` (use an allocator of the underlying system). This parameter was added in InnoDB storage engine 1.0.3. See [Section 13.4.7.3, “Using Operating System Memory Allocators”](#) for more information.

- `innodb_write_io_threads`

The number of background I/O threads used for writes. The allowable value range is `1` to `64` and the default value is `4`. This parameter was added in InnoDB storage engine 1.0.4. See [Section 13.4.7.8, “Multiple Background I/O Threads”](#) for more information.

### 13.4.14.2. Deprecated Parameters

Beginning in InnoDB storage engine 1.0.4, the following configuration parameter has been removed:

- `innodb_file_io_threads`

This parameter has been replaced by two new parameters `innodb_read_io_threads` and `innodb_write_io_threads`. See [Section 13.4.7.8, “Multiple Background I/O Threads”](#) for more information.

### 13.4.14.3. Parameters with New Defaults

For better out-of-the-box performance, the following InnoDB configuration parameters have new default values since MySQL 5.1:

**Table 13.9. InnoDB Parameters with New Defaults**

Name	Old Default	New Default
<code>innodb_additional_mem_pool_size</code>	1MB	8MB
<code>innodb_buffer_pool_size</code>	8MB	128MB
<code>innodb_change_buffering</code>	<code>inserts</code>	<code>all</code>
<code>innodb_file_format_check</code>	<code>ON</code>	<code>1</code>
<code>innodb_log_buffer_size</code>	1MB	8MB
<code>innodb_max_dirty_pages_pct</code>	90	75
<code>innodb_sync_spin_loops</code>	20	30
<code>innodb_thread_concurrency</code>	8	0

## 13.5. The **MyISAM** Storage Engine

Before MySQL 5.5.5, **MyISAM** is the default storage engine. (The default was changed to **InnoDB** in MySQL 5.5.5.) **MyISAM** is based on the older (and no longer available) **ISAM** storage engine but has many useful extensions.

**Table 13.10. **MyISAM** Storage Engine Features**

Storage limits	256TB	Transactions	No	Locking granularity	Table
MVCC	No	Geospatial data type sup-	Yes	Geospatial indexing sup-	Yes

		port		port	
<b>B-tree indexes</b>	Yes	<b>Hash indexes</b>	No	<b>Full-text search indexes</b>	Yes
<b>Clustered indexes</b>	No	<b>Data caches</b>	No	<b>Index caches</b>	Yes
<b>Compressed data</b>	Yes <sup>a</sup>	<b>Encrypted data</b> <sup>b</sup>	Yes	<b>Cluster database support</b>	No
<b>Replication support</b> <sup>c</sup>	Yes	<b>Foreign key support</b>	No	<b>Backup / point-in-time recovery</b> <sup>d</sup>	Yes
<b>Query cache support</b>	Yes	<b>Update statistics for data dictionary</b>	Yes		

<sup>a</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>b</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage product.

<sup>d</sup>Implemented in the server, rather than in the storage product.

Each **MyISAM** table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` (**MYData**) extension. The index file has an `.MYI` (**MYIndex**) extension.

To specify explicitly that you want a **MyISAM** table, indicate that with an **ENGINE** table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

As of MySQL 5.5.5, it is normally necessary to use **ENGINE** to specify the **MyISAM** storage engine because **InnoDB** is the default engine. Before 5.5.5, this is unnecessary because **MyISAM** is the default engine unless the default has been changed. To ensure that **MyISAM** is used in situations where the default might have been changed, include the **ENGINE** option explicitly.

You can check or repair **MyISAM** tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress **MyISAM** tables with `myisampack` to take up much less space. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), and [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

**MyISAM** tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of  $(2^{32})^2$  (1.844E+19) rows in a **MyISAM** table.
- The maximum number of indexes per **MyISAM** table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an **AUTO\_INCREMENT** column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one **AUTO\_INCREMENT** column per table is supported. **MyISAM** automatically updates this column for **INSERT** and **UPDATE** operations. This makes **AUTO\_INCREMENT** columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an **AUTO\_INCREMENT** column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The **AUTO\_INCREMENT** value can be reset with **ALTER TABLE** or `myisamchk`.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- **MyISAM** supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can **INSERT** new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 7.10.3, “Concurrent Inserts”](#).
- You can put the data file and index file in different directories on different physical devices to get more speed with the **DATA DIRECTORY** and **INDEX DIRECTORY** table options to **CREATE TABLE**. See [Section 12.1.17, “CREATE TABLE Syntax”](#).
- **BLOB** and **TEXT** columns can be indexed.
- **NULL** values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Section 9.1, “Character Set Support”](#).
- There is a flag in the **MyISAM** index file that indicates whether the table was closed correctly. If **mysqld** is started with the **-myisam-recover-options** option, **MyISAM** tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- **myisamchk** marks tables as checked if you run it with the **--update-state** option. **myisamchk --fast** checks only those tables that don't have this mark.
- **myisamchk --analyze** stores statistics for portions of keys, as well as for entire keys.
- **myisampack** can pack **BLOB** and **VARCHAR** columns.

**MyISAM** also supports the following features:

- Support for a true **VARCHAR** type; a **VARCHAR** column starts with a length stored in one or two bytes.
- Tables with **VARCHAR** columns may have fixed or dynamic row length.
- The sum of the lengths of the **VARCHAR** and **CHAR** columns in a table may be up to 64KB.
- Arbitrary length **UNIQUE** constraints.

## Additional Resources

- A forum dedicated to the **MyISAM** storage engine is available at <http://forums.mysql.com/list.php?21>.

### 13.5.1. **MyISAM** Startup Options

The following options to **mysqld** can be used to change the behavior of **MyISAM** tables. For additional information, see [Section 5.1.2, “Server Command Options”](#).

**Table 13.11. **MyISAM** Option/Variable Reference**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">bulk_insert_buffer_size</a>	Yes	Yes	Yes		Both	Yes
<a href="#">concurrent_insert</a>	Yes	Yes	Yes		Global	Yes
<a href="#">delay-key-write</a>	Yes	Yes			Global	Yes
- Variable: <a href="#">delay_key_write</a>			Yes		Global	Yes
<a href="#">have_rtree_keys</a>			Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">key_buffer_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">log-isam</a>	Yes	Yes				
<a href="#">myisam-block-size</a>	Yes	Yes				
<a href="#">myisam_data_pointer_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">myisam_max_sort_file_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">myisam_mmap_size</a>	Yes	Yes	Yes		Global	No
<a href="#">myisam-recover</a>	Yes	Yes				
- Variable: myisam_recover_options						
<a href="#">myisam-recover-options</a>	Yes	Yes				
- Variable: myisam_recover_options						
<a href="#">myisam_recover_options</a>			Yes		Global	No
<a href="#">myisam_repair_threads</a>	Yes	Yes	Yes		Both	Yes
<a href="#">myisam_sort_buffer_size</a>	Yes	Yes	Yes		Both	Yes
<a href="#">myisam_stats_method</a>	Yes	Yes	Yes		Both	Yes
<a href="#">myisam_use_mmap</a>	Yes	Yes	Yes		Global	Yes
<a href="#">skip-concurrent-insert</a>	Yes	Yes				
- Variable: concurrent_insert						
<a href="#">tmp_table_size</a>	Yes	Yes	Yes		Both	Yes

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed **MyISAM** tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any **MyISAM** table.

### Note

If you do this, you should not access **MyISAM** tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of **MyISAM** tables. For additional information, see [Section 5.1.3, “Server System Variables”](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization.

### Note

This is a limit *per thread*!

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is permitted to use while re-creating a **MyISAM** index (during **REPAIR TABLE**, **ALTER TABLE**, or **LOAD DATA INFILE**). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a **MyISAM** table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify **FORCE** in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify **FORCE**, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

Note that if the automatic recovery value includes **BACKUP**, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a **cron** script that automatically moves these files from the database directories to backup media.

## 13.5.2. Space Needed for Keys

**MyISAM** tables use B-tree indexes. You can roughly calculate the size for the index file as  $(key\_length+4)/0.67$ , summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a **VARCHAR** column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In **MyISAM** tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 13.5.3. **MyISAM** Table Storage Formats

**MyISAM** supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 4.6.5](#), “`myisampack` — Generate Compressed, Read-Only **MyISAM** Tables”).

When you use **CREATE TABLE** or **ALTER TABLE** for a table that has no **BLOB** or **TEXT** columns, you can force the table format to **FIXED** or **DYNAMIC** with the `ROW_FORMAT` table option.

See [Section 12.1.17](#), “**CREATE TABLE Syntax**”, for information about `ROW_FORMAT`.

You can decompress (unpack) compressed **MyISAM** tables using `myisamchk --unpack`; see [Section 4.6.3](#), “`myisamchk` — **My-**

ISAM Table-Maintenance Utility”, for more information.

### 13.5.3.1. Static (Fixed-Length) Table Characteristics

Static format is the default for **MyISAM** tables. It is used when the table contains no variable-length columns (**VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT**). Each row is stored using a fixed number of bytes.

Of the three **MyISAM** storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format **MyISAM** file. In this case, **myisamchk** can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. Note that **MyISAM** table indexes can always be reconstructed based on the data rows.

#### Note

Fixed-length row format is only available for tables without **BLOB** or **TEXT** columns. Creating a table with these columns with an explicit **ROW\_FORMAT** clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- **CHAR** and **VARCHAR** columns are space-padded to the specified column width, although the column type is not altered. **BINARY** and **VARBINARY** columns are padded with **0x00** bytes to the column width.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use **OPTIMIZE TABLE** or **myisamchk -r**.
- Usually require more disk space than dynamic-format tables.

### 13.5.3.2. Dynamic Table Characteristics

Dynamic storage format is used if a **MyISAM** table contains any variable-length columns (**VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT**), or if the table was created with the **ROW\_FORMAT=DYNAMIC** table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use **OPTIMIZE TABLE** or **myisamchk -r** to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain **NULL** values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run **OPTIMIZE TABLE** or **myisamchk -r** from time to time to improve performance.

Use `myisamchk -ei` to obtain table statistics.

- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 13.5.3.3. Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `mysampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

#### Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

### 13.5.4. MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

#### 13.5.4.1. Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 12.7.2.2, “CHECK TABLE Syntax”](#), [Section 12.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section C.5.4.2, “What to Do If MySQL Keeps Crashing”](#), and [MySQL Internals: Porting](#).

### 13.5.4.2. Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)

- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

## 13.6. The **MEMORY** Storage Engine

The **MEMORY** storage engine (formerly known as **HEAP**) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

**Table 13.12. **MEMORY** Storage Engine Features**

Storage limits	RAM	Transactions	No	Locking granularity	Table
MVCC	No	Geospatial data type support	No	Geospatial indexing support	No
B-tree indexes	Yes	Hash indexes	Yes	Full-text search indexes	No
Clustered indexes	No	Data caches	N/A	Index caches	N/A
Compressed data	No	Encrypted data <sup>a</sup>	Yes	Cluster database support	No
Replication support <sup>b</sup>	Yes	Foreign key support	No	Backup / point-in-time recovery <sup>c</sup>	Yes
Query cache support	Yes	Update statistics for data dictionary	Yes		

<sup>a</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>b</sup>Implemented in the server, rather than in the storage product.

<sup>c</sup>Implemented in the server, rather than in the storage product.

**When to Use **MEMORY** or MySQL Cluster.** Developers looking to deploy applications that use the **MEMORY** storage engine for important, highly available, or frequently updated data should consider whether MySQL Cluster is a better choice. A typical use case for the **MEMORY** engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in **MEMORY** tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the **MEMORY** engine with higher performance levels, and provides additional features not available with **MEMORY**:

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.

- Support for variable-length data types (including [BLOB](#) and [TEXT](#)) not supported by [MEMORY](#).

For a white paper with more detailed comparison of the [MEMORY](#) storage engine and MySQL Cluster, see [Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine](#). This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing [MEMORY](#) users can migrate to MySQL Cluster.

## Performance Characteristics

[MEMORY](#) performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for [MEMORY](#) tables, they are not necessarily faster than [InnoDB](#) tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of [MEMORY](#) tables from multiple sessions.

Depending on the kinds of queries performed on a [MEMORY](#) table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

## Physical Characteristics of [MEMORY](#) Tables

The [MEMORY](#) storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of `.frm`.

[MEMORY](#) tables have the following characteristics:

- Space for [MEMORY](#) tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. [MEMORY](#) tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- [MEMORY](#) tables use a fixed-length row-storage format. Variable-length types such as [VARCHAR](#) are stored using a fixed length.
- [MEMORY](#) tables cannot contain [BLOB](#) or [TEXT](#) columns.
- [MEMORY](#) includes support for [AUTO\\_INCREMENT](#) columns.
- Non-[TEMPORARY MEMORY](#) tables are shared among all clients, just like any other non-[TEMPORARY](#) table.

## DDL Operations for [MEMORY](#) Tables

To create a [MEMORY](#) table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, [MEMORY](#) tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in [MEMORY](#) tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a [MEMORY](#) table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
-> SELECT ip,SUM(downloads) AS down
-> FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of [MEMORY](#) tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for [MEMORY](#) tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maxim-

um size of existing **MEMORY** tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

## Indexes

The **MEMORY** storage engine supports both **HASH** and **BTREE** indexes. You can specify one or the other for a given index by adding a **USING** clause as shown here:

```
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 7.3.1, “How MySQL Uses Indexes”](#).

**MEMORY** tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a **MEMORY** table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.

**MEMORY** tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain **NULL** values.

## User-Created and Temporary Tables

**MEMORY** table contents are stored in memory, which is a property that **MEMORY** tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that **MEMORY** tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 7.4.3.3, “How MySQL Uses Internal Temporary Tables”](#).
- User-created **MEMORY** tables are never converted to disk tables.

## Loading Data

To populate a **MEMORY** table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.1.2, “Server Command Options”](#), and [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).

For loading data into **MEMORY** tables accessed by other sessions concurrently, **MEMORY** supports `INSERT DELAYED`. See [Section 12.2.5.2, “INSERT DELAYED Syntax”](#).

## **MEMORY** Tables and Replication

A server's **MEMORY** tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave **MEMORY** tables, when a **MEMORY** table is used on a master for the first time since it was started, a `DELETE` statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the **MEMORY** table on the master at startup.

## Managing Memory Use

The server needs sufficient memory to maintain all **MEMORY** tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a **MEMORY** table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a **MEMORY** table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the

table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

## Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

## 13.7. The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it to the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i    | c          |
+-----+-----+
| 1    | record one |
| 2    | record two |
+-----+-----+
2 rows in set (0.00 sec)
```

Creating a `CSV` table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the ta-

ble. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

### 13.7.1. Repairing and Checking CSV Tables

The CSV storage engine supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | error    | Corrupt  |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | warning  | Table is marked as crashed |
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

#### Warning

Note that during repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

### 13.7.2. CSV Limitations

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the [CSV](#) storage engine.

Tables using the [CSV](#) storage engine cannot be created with [NULL](#) columns. However, for backward compatibility, you can continue to use such tables that were created in previous MySQL releases. (Bug #32050)

## 13.8. The [ARCHIVE](#) Storage Engine

The [ARCHIVE](#) storage engine is used for storing large amounts of data without indexes in a very small footprint.

**Table 13.13. [ARCHIVE](#) Storage Engine Features**

<b>Storage limits</b>	None	<b>Transactions</b>	No	<b>Locking granularity</b>	Table
<b>MVCC</b>	No	<b>Geospatial data type support</b>	Yes	<b>Geospatial indexing support</b>	No
<b>B-tree indexes</b>	No	<b>Hash indexes</b>	No	<b>Full-text search indexes</b>	No
<b>Clustered indexes</b>	No	<b>Data caches</b>	No	<b>Index caches</b>	No
<b>Compressed data</b>	Yes	<b>Encrypted data<sup>a</sup></b>	Yes	<b>Cluster database support</b>	No
<b>Replication support<sup>b</sup></b>	Yes	<b>Foreign key support</b>	No	<b>Backup / point-in-time recovery<sup>c</sup></b>	Yes
<b>Query cache support</b>	Yes	<b>Update statistics for data dictionary</b>	Yes		

<sup>a</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>b</sup>Implemented in the server, rather than in the storage product.

<sup>c</sup>Implemented in the server, rather than in the storage product.

The [ARCHIVE](#) storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke [CMake](#) with the [-DWITH\\_ARCHIVE\\_STORAGE\\_ENGINE](#) option.

To examine the source for the [ARCHIVE](#) engine, look in the [storage/archive](#) directory of a MySQL source distribution.

You can check whether the [ARCHIVE](#) storage engine is available with the [SHOW ENGINES](#) statement.

When you create an [ARCHIVE](#) table, the server creates a table format file in the database directory. The file begins with the table name and has an [.frm](#) extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of [.ARZ](#). An [.ARN](#) file may appear during optimization operations.

The [ARCHIVE](#) engine supports [INSERT](#) and [SELECT](#), but not [DELETE](#), [REPLACE](#), or [UPDATE](#). It does support [ORDER BY](#) operations, [BLOB](#) columns, and basically all but spatial data types (see [Section 11.17.4.1, “MySQL Spatial Data Types”](#)). The [ARCHIVE](#) engine uses row-level locking.

The [ARCHIVE](#) engine supports the [AUTO\\_INCREMENT](#) column attribute. The [AUTO\\_INCREMENT](#) column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The [ARCHIVE](#) engine also supports the [AUTO\\_INCREMENT](#) table option in [CREATE TABLE](#) and [ALTER TABLE](#) statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

The [ARCHIVE](#) engine ignores [BLOB](#) columns if they are not requested and scans past them while reading.

**Storage:** Rows are compressed as they are inserted. The [ARCHIVE](#) engine uses [zlib](#) lossless data compression (see <http://www.zlib.net/>). You can use [OPTIMIZE TABLE](#) to analyze the table and pack it into a smaller format (for a reason to use [OPTIMIZE TABLE](#), see later in this section). The engine also supports [CHECK TABLE](#). There are several types of insertions that are used:

- An [INSERT](#) statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A [SELECT](#) forces a flush to occur, unless the only insertions that have come in were [INSERT DELAYED](#) (those flush as necessary). See [Section 12.2.5.2, “INSERT DELAYED Syntax”](#).
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A [SELECT](#) never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 12.7.2.4, “OPTIMIZE TABLE Syntax”](#), [Section 12.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 12.7.5.37, “SHOW TABLE STATUS Syntax”](#).

## Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

## 13.9. The `BLACKHOLE` Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

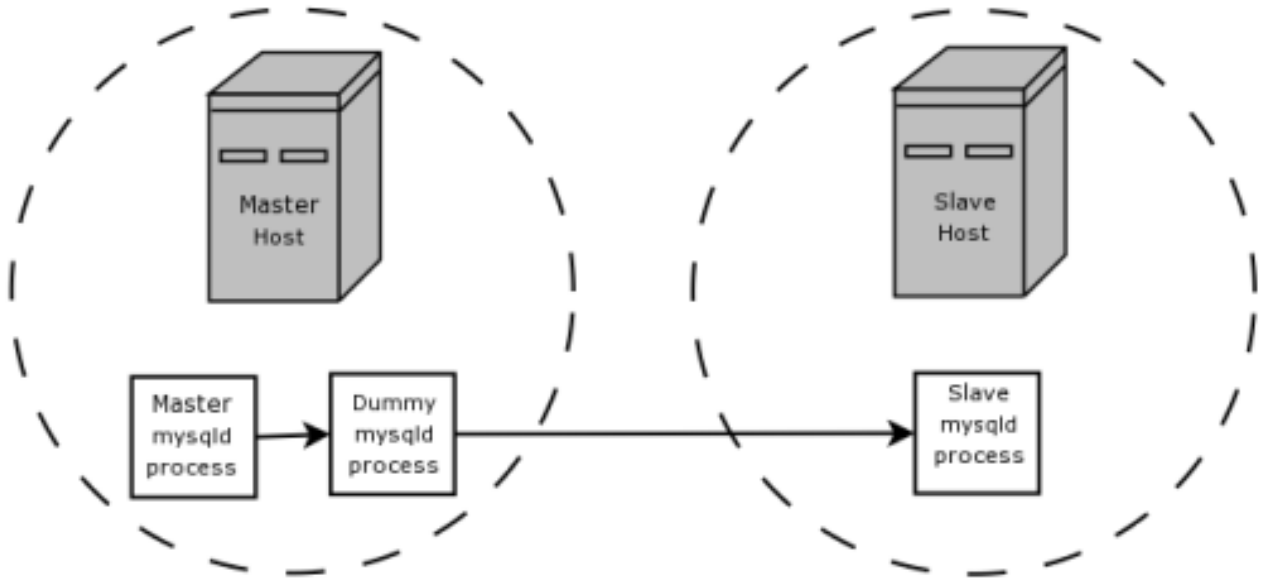

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a `BLACKHOLE` table do not store any data, but if the binary log is enabled, the SQL statements are logged (and replicated to slave servers). This can be useful as a repeater or filter mechanism. Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is `BLACKHOLE`, depicted as follows:

The master writes to its binary log. The “dummy” `mysql` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysql` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

### Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

### Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section [Section 15.4.1.6, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how master table filtering is achieved - by using the `BLACKHOLE` engine and the option `--replicate-[do|ignore]-table`.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

## 13.10. The `MERGE` Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

An alternative to a `MERGE` table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the `MyISAM` storage engine. For more information, see [Chapter 17, Partitioning](#).

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the underlying `MyISAM` tables that should be used as one. The tables do not have to be in the same database as the `MERGE` table.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `DELETE`, and `UPDATE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

### Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a [MERGE](#) table, you must specify a `UNION=(list-of-tables)` option that indicates which [MyISAM](#) tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the [MERGE](#) table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the [MERGE](#) table are not permitted and attempts to do so result in an error.

The following example shows how to create a [MERGE](#) table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Note that column `a` is indexed as a [PRIMARY KEY](#) in the underlying [MyISAM](#) tables, but not in the [MERGE](#) table. There it is indexed but not as a [PRIMARY KEY](#) because a [MERGE](#) table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a [UNIQUE](#) index in the underlying tables should be indexed in the [MERGE](#) table but not as a [UNIQUE](#) index.)

After creating the [MERGE](#) table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+----+-----+
| a | message |
+----+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+----+-----+
```

To remap a [MERGE](#) table to a different collection of [MyISAM](#) tables, you can use one of the following methods:

- `DROP` the [MERGE](#) table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables.

The underlying table definitions and indexes must conform closely to the definition of the [MERGE](#) table. Conformance is checked when a table that is part of a [MERGE](#) table is opened, not when the [MERGE](#) table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a [MERGE](#) may cause a failure when the [MERGE](#) table is accessed. The conformance checks applied to each table are:

- The underlying table and the [MERGE](#) table must have the same number of columns.
- The column order in the underlying table and the [MERGE](#) table must match.
- Additionally, the specification for each corresponding column in the parent [MERGE](#) table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the [MERGE](#) table must be equal.
  - The column length in the underlying table and the [MERGE](#) table must be equal.
  - The column of the underlying table and the [MERGE](#) table can be `NULL`.
- The underlying table must have at least as many indexes as the [MERGE](#) table. The underlying table may have more indexes than the [MERGE](#) table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the **MERGE** table and the underlying **MyISAM** table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the **MERGE** table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the **MERGE** table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
  - Check whether index parts can be **NULL**.

If a **MERGE** table cannot be opened or used because of a problem with an underlying table, **CHECK TABLE** displays information about which table caused the problem.

## Additional Resources

- A forum dedicated to the **MERGE** storage engine is available at <http://forums.mysql.com/list.php?93>.

### 13.10.1. **MERGE** Table Advantages and Disadvantages

**MERGE** tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with **myisampack**, and then create a **MERGE** table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A **MERGE** table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a **MERGE** table for others. You can even have many different **MERGE** tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a **MERGE** table than to repair a single large table.
- Instantly map many tables as one. A **MERGE** table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, **MERGE** table collections are *very* fast to create or remap. (You must still specify the index definitions when you create a **MERGE** table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a **MERGE** table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each **MyISAM** table is bound by this limit, but a collection of **MyISAM** tables is not.
- You can create an alias or synonym for a **MyISAM** table by defining a **MERGE** table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and **memcpy**( ) calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.
- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)
- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.
- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 12.8.2, “EXPLAIN Syntax”](#).

### 13.10.2. `MERGE` Table Problems

The following are known problems with `MERGE` tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child `MyISAM` tables.  
  
From versions 5.1.23, `MERGE` children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the `MyISAM` tables corrupted them.
- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after

one of the named operations on the underlying **MyISAM** tables, the corruption message is spurious. To deal with this, issue a **FLUSH TABLES** statement after modifying the **MyISAM** tables.

- **DROP TABLE** on a table that is in use by a **MERGE** table does not work on Windows because the **MERGE** storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all **MERGE** tables (with **FLUSH TABLES**) or drop the **MERGE** table before dropping the table.
- The definition of the **MyISAM** tables and the **MERGE** table are checked when the tables are accessed (for example, as part of a **SELECT** or **INSERT** statement). The checks ensure that the definitions of the tables and the parent **MERGE** table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.
- The order of indexes in the **MERGE** table and its underlying tables should be the same. If you use **ALTER TABLE** to add a **UNIQUE** index to a table used in a **MERGE** table, and then use **ALTER TABLE** to add a nonunique index on the **MERGE** table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because **ALTER TABLE** puts **UNIQUE** indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to **ERROR 1017 (HY000): CAN'T FIND FILE: 'TBL\_NAME.MRG' (ERRNO: 2)**, it generally indicates that some of the underlying tables do not use the **MyISAM** storage engine. Confirm that all of these tables are **MyISAM**.
- The maximum number of rows in a **MERGE** table is  $2^{64}$  (~1.844E+19; the same as for a **MyISAM** table). It is not possible to merge multiple **MyISAM** tables into a single **MERGE** table that would have more than this number of rows.
- The **MERGE** storage engine does not support **INSERT DELAYED** statements.
- Use of underlying **MyISAM** tables of differing row formats with a parent **MERGE** table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary **MERGE** table when **LOCK TABLES** is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary **MERGE** table.

- You cannot create a **MERGE** table with **CREATE ... SELECT**, neither as a temporary **MERGE** table, nor as a nontemporary **MERGE** table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: *tbl\_name* is not **BASE TABLE**.

- In some cases, differing **PACK\_KEYS** table option values among the **MERGE** and underlying tables cause unexpected results if the underlying tables contain **CHAR** or **BINARY** columns. As a workaround, use **ALTER TABLE** to ensure that all involved tables have the same **PACK\_KEYS** value. (Bug #50646)

## 13.11. The **FEDERATED** Storage Engine

The **FEDERATED** storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local **FEDERATED** table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the **FEDERATED** storage engine if you build MySQL from source, invoke **CMake** with the **-DWITH\_FEDERATED\_STORAGE\_ENGINE** option.

The **FEDERATED** storage engine is not enabled by default in the running server; to enable **FEDERATED**, you must start the MySQL server binary using the **--federated** option.

To examine the source for the **FEDERATED** engine, look in the **storage/federated** directory of a MySQL source distribution.

### 13.11.1. FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as [MyISAM](#), [CSV](#) or [InnoDB](#)), the table consists of the table definition and the associated data. When you create a [FEDERATED](#) table, the table definition is the same, but the physical storage of the data is handled on a remote server.

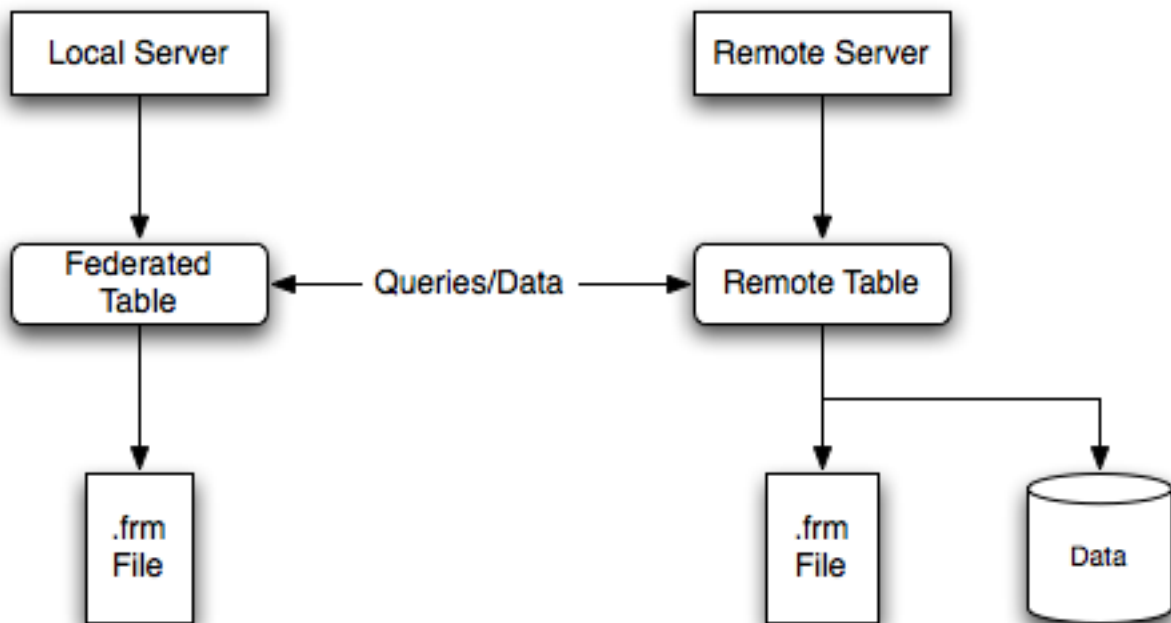

A [FEDERATED](#) table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the [.frm](#) file) and the associated table. The table type of the remote table may be any type supported by the remote [mysqld](#) server, including [MyISAM](#) or [InnoDB](#).
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the [.frm](#) file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a [FEDERATED](#) table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a [FEDERATED](#) table setup is shown in [Figure 13.2, “FEDERATED Table Structure”](#).

**Figure 13.2. FEDERATED Table Structure**

When a client issues an SQL statement that refers to a [FEDERATED](#) table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the [FEDERATED](#) table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the **FEDERATED** engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

### 13.11.2. How to Create **FEDERATED** Tables

To create a **FEDERATED** table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the **CONNECTION**, or you can use an existing connection that you have previously created using the **CREATE SERVER** statement.

#### Important

When you create the local table it *must* have an identical field definition to the remote table.

#### Note

You can improve the performance of a **FEDERATED** table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the **WHERE** clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

#### 13.11.2.1. Creating a **FEDERATED** Table Using **CONNECTION**

To use the first method, you must specify the **CONNECTION** string after the engine type in a **CREATE TABLE** statement. For example:

```
CREATE TABLE federated_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

#### Note

**CONNECTION** replaces the **COMMENT** used in some previous versions of MySQL.

The **CONNECTION** string contains the information required to connect to the remote server containing the table that will be used to

physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- `scheme`: A recognized connection protocol. Only `mysql` is supported as the `scheme` value at this point.
- `user_name`: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- `password`: (Optional) The corresponding password for `user_name`.
- `host_name`: The host name or IP address of the remote server.
- `port_num`: (Optional) The port number for the remote server. The default is 3306.
- `db_name`: The name of the database holding the remote table.
- `tbl_name`: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 13.11.2.2. Creating a **FEDERATED** Table Using **CREATE SERVER**

If you are creating a number of **FEDERATED** tables on the same server, or if you want to simplify the process of creating **FEDERATED** tables, you can use the **CREATE SERVER** statement to define the server connection parameters, just as you would with the **CONNECTION** string.

The format of the **CREATE SERVER** statement is:

```
CREATE SERVER server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The `server_name` is used in the connection string when creating a new **FEDERATED** table.

For example, to create a server connection identical to the **CONNECTION** string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a **FEDERATED** table that uses this connection, you still use the **CONNECTION** keyword, but specify the name you used in the **CREATE SERVER** statement.

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
```

```
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see [Section 12.1.16, “CREATE SERVER Syntax”](#).

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Connection scheme	<i>scheme</i>	<i>wrapper_name</i>	Wrapper
Remote user	<i>user_name</i>	USER	Username
Remote password	<i>password</i>	PASSWORD	Password
Remote host	<i>host_name</i>	HOST	Host
Remote port	<i>port_num</i>	PORT	Port
Remote database	<i>db_name</i>	DATABASE	Db

### 13.11.3. FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes per se. Because access to the table is handled remotely, it is the remote table that supports the indexes. Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns will fail. The following definition in `MyISAM` is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the `FEDERATED` engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.
- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, and indexes. It does not

support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.

- `FEDERATED` accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a `FEDERATED` table when performing bulk inserts (for example, on a `INSERT INTO ... SELECT ...` statement) is slower than with other table types because each selected row is treated as an individual `INSERT` statement on the `FEDERATED` table.
- Transactions are not supported.
- `FEDERATED` performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
  - Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.
- There is no way for the `FEDERATED` engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a `CONNECTION` string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.
- The `insert_id` and `timestamp` options are not propagated to the data provider.
- Any `DROP TABLE` statement issued against a `FEDERATED` table drops only the local table, not the remote table.
- `FEDERATED` tables do not work with the query cache.
- User-defined partitioning is not supported for `FEDERATED` tables.

### 13.11.4. `FEDERATED` Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

## 13.12. The `EXAMPLE` Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The [EXAMPLE](#) storage engine does not support indexing.

## 13.13. Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

You can find more information on the list of third party storage engines on the [MySQL Forge Storage Engines](#) page.

### Note

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

Third party engines that are known to be available include the following; please see the MySQL Forge links provided for more information:

- **PrimeBase XT (PBXT)**: PBXT has been designed for modern, web-based, high concurrency environments.
- **RitmarkFS**: RitmarkFS enables you to access and manipulate the file system using SQL queries. RitmarkFS also supports file system replication and directory change tracking.
- **Distributed Data Engine**: The Distributed Data Engine is an Open Source project that is dedicated to provide a Storage Engine for distributed data according to workload statistics.
- **mdbtools**: A pluggable storage engine that enables read-only access to Microsoft Access `.mdb` database files.
- **solidDB for MySQL**: solidDB Storage Engine for MySQL is an open source, transactional storage engine for MySQL Server. It is designed for mission-critical implementations that require a robust, transactional database. solidDB Storage Engine for MySQL is a multi-threaded storage engine that supports full ACID compliance with all expected transaction isolation levels, row-level locking, and Multi-Version Concurrency Control (MVCC) with nonblocking reads and writes.
- **BLOB Streaming Engine (MyBS)**: The Scalable BLOB Streaming infrastructure for MySQL will transform MySQL into a scalable media server capable of streaming pictures, films, MP3 files and other binary and text objects (BLOBs) directly in and out of the database.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [Writing a Custom Storage Engine](#) on [MySQL Forge](#).

MySQL is deployed into many applications demanding availability and scalability.

Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Scalability refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: <http://dev.mysql.com/doc/refman/5.5/en/replication.html>

- MySQL Cluster. Learn more: <http://dev.mysql.com/doc/refman/5.1/en/mysql-cluster.html>
- Oracle VM Template for MySQL. Learn more: [Section 14.1, “Oracle VM Template for MySQL Enterprise Edition”](#).

Further options are available using third-party solutions such as DRBD (Distributed Replicated Block Device) and Heartbeat, and more complex scenarios can be solved through a combination of these technologies.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

**Figure 14.1. Tradeoffs: Cost and Complexity versus Availability**

The following figure maps common application types to architectures, based on best practices observed from the MySQL user base. It serves as a reference point to investigate which HA architectures can best serve your requirements.

**Figure 14.2. High Availability Architectures for Common Application Types**

Applications	Data Replication	Clustered / Virtualized	Shared-Nothing, Geo-Replicated Cluster
E-Commerce / Trading		⊙	⊙
Session Management		⊙	⊙
User Authentication / Accounting		⊙	⊙
Feeds, Blogs, Wikis	⊙	⊙	
Websites	⊙	⊙	
OLTP		⊙	⊙
Data Warehouse/BI	⊙	⊙	
Content Management	⊙	⊙	
CRM		⊙	
Collaboration	⊙	⊙	
Packaged Software		⊙	
Telco Apps (HLR/HSS/SDP...)			⊙

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

Requirement	MySQL Replication	MySQL Replication + Linux Heartbeat	Heartbeat + DRBD	Oracle VM Template	MySQL Cluster
<b>Availability</b>					
Platform Support	All Supported by MySQL Server	Linux	Linux	Oracle Linux	All Supported by MySQL Cluster
Automated IP Failover	No	Yes	Yes	Yes	Depends on Connector and Configuration
Automated Database Failover	No	No	Yes	Yes	Yes
Automatic Data Resynchronization	No	No	Yes	N/A - Shared Storage	Yes
Typical Failover Time	User / Script Dependent	Configuration Dependent, 60 seconds and Above	Configuration Dependent, 60 seconds and Above	Configuration Dependent, 60 seconds and Above	1 Second and Less
Synchronous Replication	No, Asynchronous and Semisynchronous	No, Asynchronous and Semisynchronous	Yes	N/A - Shared Storage	Yes
Shared Storage	No, Distributed	No, Distributed	No, Distributed	Yes	No, Distributed
Geographic redundancy support	Yes	Yes	Yes, via MySQL Replication	Yes, via MySQL Replication	Yes, via MySQL Replication

Requirement	MySQL Replication	MySQL Replication + Linux Heartbeat	Heartbeat + DRBD	Oracle VM Template	MySQL Cluster
Update Schema On-Line	No	No	No	No	Yes
<b>Scalability</b>					
Number of Nodes	One Master, Multiple Slaves	One Master, Multiple Slaves	One Active (primary), one Passive (secondary) Node	One Active (primary), one Passive (secondary) Node	255
Built-in Load Balancing	Reads, via MySQL Replication	Reads, via MySQL Replication	Reads, via MySQL Replication	Reads, via MySQL Replication & During Failover	Yes, Reads and Writes
Supports Read-Intensive Workloads	Yes	Yes	Yes	Yes	Yes
Supports Write-Intensive Workloads	Yes, via Application-Level Sharding	Yes, via Application-Level Sharding	Yes, via Application-Level Sharding to Multiple Active/Passive Pairs	Yes, via Application-Level Sharding to Multiple Active/Passive Pairs	Yes, via Auto-Sharding
Scale On-Line (add nodes, repartition, etc.)	No	No	No	No	Yes

## 14.1. Oracle VM Template for MySQL Enterprise Edition

Virtualization is a key technology to enable data center efficiency and high availability while providing the foundation for cloud computing. Integrating MySQL Enterprise Edition with Oracle Linux, the Oracle VM Template is the fastest, easiest, and most reliable way to provision virtualized MySQL instances, enabling users to meet the explosive demand for highly available services.

The Oracle VM Template enables rapid deployment and eliminates manual configuration efforts. It provides a pre-installed and pre-configured virtualized MySQL 5.5 Enterprise Edition software image running on Oracle Linux and Oracle VM, certified for production use. The MySQL software image has undergone extensive integration and quality assurance testing as part of the development process.

In addition to rapid provisioning, MySQL users also benefit from the integrated high availability features of Oracle VM which are designed to enable organizations to meet stringent SLA (Service Level Agreement) demands through a combination of:

- **Automatic recovery from failures**, with Oracle VM automatically restarting failed instances on available servers in the server pool after outages of the physical server, VM or MySQL database.
- **Live Migration**, enabling operations staff to move running instances of MySQL to alternative hosts within a server pool during maintenance operations.

Instructions for the creation, deployment and use of the Oracle VM Template for MySQL Enterprise Edition are available from:

- The Oracle VM Template for MySQL Enterprise Edition whitepaper: [http://www.mysql.com/why-mysql/white-papers/mysql\\_wp\\_oracle-vm-template-for-mee.php](http://www.mysql.com/why-mysql/white-papers/mysql_wp_oracle-vm-template-for-mee.php).
- The README file accompanying the download of the Template.

To download the Oracle VM Template for MySQL Enterprise, go to <http://edelivery.oracle.com/oraclevm> and follow these instructions:

- Complete your registration information (Name, Company Name, Email Address and Country) and click on the download agreement.
- Select "Oracle VM Templates" from the "Select a Product Pack" pull-down menu and click "Go".
- Select MySQL Enterprise from the list of Oracle VM Templates.

- Download and unzip the files and refer to the README for further instructions.

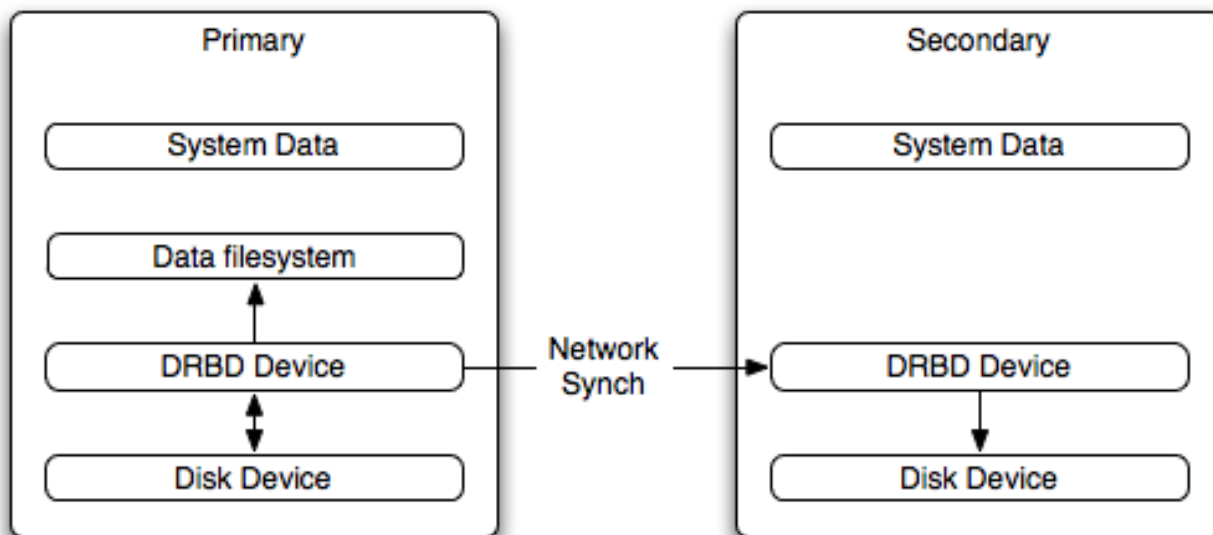

## 14.2. Using MySQL with DRBD

The Distributed Replicated Block Device (DRBD) is a Linux Kernel module that constitutes a distributed storage system. You can use DRBD to share block devices between Linux servers and, in turn, share file systems and data.

DRBD implements a block device which can be used for storage and which is replicated from a primary server to one or more secondary servers. The distributed block device is handled by the DRBD service. Writes to the DRBD block device are distributed among the servers. Each DRBD service writes the information from the DRBD block device to a local physical block device (hard disk).

On the primary data writes are written both to the underlying physical block device and distributed to the secondary DRBD services. On the secondary, the writes received through DRBD and written to the local physical block device. On both the primary and the secondary, reads from the DRBD block device are handled by the underlying physical block device. The information is shared between the primary DRBD server and the secondary DRBD server synchronously and at a block level, and this means that DRBD can be used in high-availability solutions where you need failover support.

**Figure 14.3. DRBD Architecture Overview**

When used with MySQL, DRBD can be used to ensure availability in the event of a failure. MySQL is configured to store information on the DRBD block device, with one server acting as the primary and a second machine available to operate as an immediate replacement in the event of a failure.

For automatic failover support, you can combine DRBD with the Linux Heartbeat project, which manages the interfaces on the two servers and automatically configures the secondary (passive) server to replace the primary (active) server in the event of a failure. You can also combine DRBD with MySQL Replication to provide both failover and scalability within your MySQL environment.

For information on how to configure DRBD and MySQL, including Heartbeat support, see [Section 14.2.1, “Configuring the DRBD Environment”](#).

For FAQs about using DRBD and MySQL, see [Section B.14, “MySQL 5.5 FAQ: MySQL, DRBD, and Heartbeat”](#).

### Note

Because DRBD is a Linux Kernel module, it is currently not supported on platforms other than Linux.

### 14.2.1. Configuring the DRBD Environment

To set up DRBD, MySQL, and Heartbeat, you follow a number of steps that affect the operating system, DRBD and your MySQL installation.

Before starting the installation process, be aware of the following information, terms and requirements on using DRBD:

- DRBD works through two (or more) servers, each called a *node*.
- Ensure that your DRBD nodes are as identically configured as possible, so that the secondary machine can act as a direct replacement for the primary machine in the event of system failure.
- The node that contains the primary data, has read/write access to the data, and in an HA environment is the currently active node is called the *primary*.
- The server to which the data is replicated is called the *secondary*.
- A collection of nodes that are sharing information is referred to as a *DRBD cluster*.
- For DRBD to operate, you must have a block device on which the information can be stored on *each* DRBD node. The lower-level block device can be a physical disk partition, a partition from a volume group or RAID device or any other block device.

Typically, you use a spare partition on which the physical data is stored. On the primary node, this disk holds the raw data that you want replicated. On the secondary nodes, the disk holds the data replicated to the secondary server by the DRBD service. Ideally, the size of the partition on the two DRBD servers should be identical, but this is not necessary as long as there is enough space to hold the data that you want distributed between the two servers.

- For the distribution of data to work, DRBD is used to create a logical block device that uses the lower level block device for the actual storage of information. To store information on the distributed device, a file system is created on the DRBD logical block device.
- When used with MySQL, once the file system has been created, you move the MySQL data directory (including InnoDB data files and binary logs) to the new file system.
- When you set up the secondary DRBD server, you set up the physical block device and the DRBD logical block device that stores the data. The block device data is then copied from the primary to the secondary server.

The overview for the installation and configuration sequence is as follows:

1. First, set up your operating system and environment. This includes setting the correct host name, updating the system and preparing the available packages and software required by DRBD, and configuring a physical block device to be used with the DRBD block device. See [Section 14.2.1.1, “Setting Up Your Operating System for DRBD”](#).
2. Installing DRBD requires installing or compiling the DRBD source code and then configuring the DRBD service to set up the block devices to be shared. See [Section 14.2.1.2, “Installing and Configuring DRBD”](#).
3. After configuring DRBD, alter the configuration and storage location of the MySQL data, as explained in [Section 14.2.2, “Configuring MySQL for DRBD”](#).

Optionally, configure high availability using the Linux Heartbeat service. See [Section 14.3, “Using Linux HA Heartbeat”](#), for more information.

### 14.2.1.1. Setting Up Your Operating System for DRBD

To set your Linux environment for using DRBD, follow these system configuration steps:

- Make sure that the primary and secondary DRBD servers have the correct host name, and that the host names are unique. You can verify this by using the `uname` command:

```
shell> uname -n
drbd-one
```

If the host name is not set correctly, edit the appropriate file (usually `/etc/sysconfig/network`, `/etc/hostname`, or `/`

`etc/conf.d/hostname`) and set the name correctly.

- Each DRBD node must have a unique IP address. Make sure that the IP address information is set correctly within the network configuration and that the host name and IP address has been set correctly within the `/etc/hosts` file.
- Although you can rely on the DNS or NIS system for host resolving, in the event of a major network failure these services may not be available. If possible, add the IP address and host name of each DRBD node into the `/etc/hosts` file for each machine. This ensures that the node information can always be determined even if the DNS/NIS servers are unavailable.
- As a general rule, the faster your network connection the better. Because the block device data is exchanged over the network, everything that is written to the local disk on the DRBD primary is also written to the network for distribution to the DRBD secondary.

For tips on configuring a faster network connection, see [Section 14.2.3, “Optimizing Performance and Reliability”](#).

- You devote a spare disk, or a partition on an existing disk, as the physical storage location for the DRBD data that is replicated.

If the disk is unpartitioned, partition the disk using `fdisk`, `cfdisk` or other partitioning solution. Do not create a file system on the new partition.

You must have a physical disk available for the storage of the replicated information on each DRBD node. Ensure that the physical partition on the DRBD secondary is at least as big as the partitions on the DRBD primary node. If possible, use identical sizes for the partitions on each node.

- If possible, upgrade your system to the latest available Linux kernel for your distribution. Once the kernel has been installed, you must reboot to make the kernel active. To use DRBD, you must also install the relevant kernel development and header files that are required for building kernel modules. Platform specification information for this is available later in this section.

Before you compile or install DRBD, make sure the following tools and files are in place:

- Kernel header files.
- Kernel source files.
- GCC Compiler.
- `glib 2` library.
- `flex` command.

Here are some operating system specific tips for setting up your installation:

- **Tips for Red Hat (including CentOS and Fedora):**

Use `up2date` or `yum` to update and install the latest kernel and kernel header files:

```
root-shell> up2date kernel-smp-devel kernel-smp
```

Reboot. If you are going to build DRBD from source, then update your system with the required development packages:

```
root-shell> up2date glib-devel openssl-devel libgcrypt-devel glib2-devel \  
pkgconfig ncurses-devel rpm-build rpm-devel redhat-rpm-config gcc \  
gcc-c++ bison flex gnutls-devel lm_sensors-devel net-snmp-devel \  
python-devel bzip2-devel libselinux-devel perl-DBI
```

If you are going to use the pre-built DRBD RPMs:

```
root-shell> up2date gnutls lm_sensors net-snmp ncurses libgcrypt glib2 openssl glib
```

- **Tips for Debian, Ubuntu, Kubuntu:**

Use `apt-get` to install the kernel packages

```
root-shell> apt-get install linux-headers linux-image-server
```

If you are going to use the pre-built Debian packages for DRBD, you do not need any additional packages.

To build DRBD from source, use the following command to install the required components:

```
root-shell> apt-get install devscripts flex bison build-essential \
dpkg-dev kernel-package debconf-utils dpatch debhelper \
libnet1-dev e2fslibs-dev libglib2.0-dev automake1.9 \
libgnutls-dev libtool libltdl3 libltdl3-dev
```

- **Tips for Gentoo:**

Gentoo is a source based Linux distribution and therefore many of the source files and components that you need are either already installed or are installed automatically by [emerge](#).

To install DRBD 0.8.x, you must unmask the `sys-cluster/drbd` build by adding the following line to `/etc/portage/package.keywords`:

```
sys-cluster/drbd ~x86
sys-cluster/drbd-kernel ~x86
```

To enable the DRBD kernel module, you must rebuild your kernel, although the method depends on the kernel version you are using. Determine your current kernel version using `uname -a`.

- For Linux kernels lower than 2.6.33, enable the userspace kernelspace linker to build and load the DRBD kernel driver. To enable the kernelspace linker, rebuild the kernel with this option. The best way to do this is to use [genkernel](#) with the `--menuconfig` option to select the option and then rebuild the kernel. For example, at the command line as `root`:

```
root-shell> genkernel --menuconfig all
```

Then through the menu options, select **DEVICE DRIVERS**, **CONNECTOR - UNIFIED USERSPACE <-> KERNELSPACE LINKER** and finally press 'y' or 'space' to select the **CONNECTOR - UNIFIED USERSPACE <-> KERNELSPACE LINKER** option. After you exit the menu configuration, the kernel is rebuilt and installed. If this is a new kernel, update your bootloader to point to the kernel if the kernel version is different than your current kernel version. Now reboot to enable the new kernel.

- For Linux Kernel 2.6.33 and later, DRBD is included within the kernel sources. To enable the DRBD module you must rebuild your kernel. The best way to do this is to use [genkernel](#) with the `--menuconfig` option to select the option and then rebuild the kernel. For example, at the command line as `root`:

```
root-shell> genkernel --menuconfig all
```

Then through the menu options, select **DEVICE DRIVERS**, **BLOCK DEVICES**, and then **DRBD DISTRIBUTED REPLICATED BLOCK DEVICE SUPPORT**. After you exit the menu configuration, the kernel is rebuilt and installed. If this is a new kernel, update your bootloader to point to the kernel if the kernel version is different than your current kernel version. Now reboot to enable the new kernel.

### 14.2.1.2. Installing and Configuring DRBD

To install DRBD, you can choose either the pre-built binary installation packages, or you can use the source packages and build from source. To build from source, you must have installed the source and development packages.

To install using a binary distribution, ensure that the kernel version number of the binary package matches your currently active kernel. You can use `uname` to find out this information:

```
shell> uname -r
2.6.20-gentoo-r6
```

Once DRBD has been built and installed, edit the `/etc/drbd.conf` file and then run a number of commands to build the block device and set up the replication.

Although the steps below are split into those for the primary node and the secondary node, the configuration files for all nodes should be

identical, and many of the same steps have to be repeated on each node to enable the DRBD block device.

Building from source:

To download and install from the source code:

1. Download the source code.
2. Unpack the package:

```
shell> tar xzf drbd-8.3.0.tar.gz
```

3. Change to the extracted directory, and then run `make` to build the DRBD driver:

```
shell> cd drbd-8.3.0
shell> make
```

4. Install the kernel driver and commands:

```
shell> make install
```

Binary Installation:

- **SUSE Linux Enterprise Server (SLES)**

For SUSE, use `yast`:

```
shell> yast -i drbd
```

Alternatively:

```
shell> rug install drbd
```

- **Debian**

Use `apt-get` to install the modules. You do not need to install any other components.

```
shell> apt-get install drbd8-utils drbd8-module
```

- **Debian 3.1 and 4.0**

You must install the `module-assistant` to build the DRBD kernel module, in addition to the DRBD components.

```
shell> apt-get install drbd0.7-utils drbd0.7-module-source \
  build-essential module-assistant
shell> module-assistant auto-install drbd0.7
```

- **CentOS**

DRBD can be installed using `yum`:

```
shell> yum install drbd kmod-drbd
```

- **Ubuntu**

Enable the universe component for your preferred Ubuntu mirror in `/etc/apt/sources.list`, then issue these commands:

```
shell> apt-get update
shell> apt-get install drbd8-utils drbd8-module-source \
  build-essential module-assistant
shell> module-assistant auto-install drbd8
```

- **Gentoo**

You can now [emerge](#) DRBD 0.8.x into your Gentoo installation:

```
root-shell> emerge drbd
```

Once [drbd](#) is downloaded and installed, decompress and copy the default configuration file from [/usr/share/doc/drbd-8.0.7/drbd.conf.bz2](#) into [/etc/drbd.conf](#).

### 14.2.1.3. Setting Up a DRBD Primary Node

To set up a DRBD primary node, configure the DRBD service, create the first DRBD block device, and then create a file system on the device so that you can store files and data.

The DRBD configuration file [/etc/drbd.conf](#) defines a number of parameters for your DRBD configuration, including the frequency of updates and block sizes, security information and the definition of the DRBD devices that you want to create.

The key elements to configure are the [on](#) sections which specify the configuration of each node.

To follow the configuration, the sequence below shows only the changes from the default [drbd.conf](#) file. Configurations within the file can be both global or tied to specific resource.

1. Set the synchronization rate between the two nodes. This is the rate at which devices are synchronized in the background after a disk failure, device replacement or during the initial setup. Keep this in check compared to the speed of your network connection. Gigabit Ethernet can support up to 125 MB/second, 100Mbps Ethernet slightly less than a tenth of that (12MBps). If you are using a shared network connection, rather than a dedicated, then gauge accordingly.

To set the synchronization rate, edit the [rate](#) setting within the [syncer](#) block:

```
syncer {  
    rate 10M;  
}
```

You may additionally want to set the [al-extents](#) parameter. The default for this parameter is 257.

For more detailed information on synchronization, the effects of the synchronization rate and the effects on network performance, see [Section 14.2.3.2, “Optimizing the Synchronization Rate”](#).

2. Set up some basic authentication. DRBD supports a simple password hash exchange mechanism. This helps to ensure that only those hosts with the same shared secret are able to join the DRBD node group.

```
cram-hmac-alg "sha1";  
shared-secret "shared-string";
```

3. Now you must configure the host information. You must have the node information for the primary and secondary nodes in the [drbd.conf](#) file on each host. Configure the following information for each node:

- [device](#): The path of the logical block device that is created by DRBD.
- [disk](#): The block device that stores the data.
- [address](#): The IP address and port number of the host that holds this DRBD device.
- [meta-disk](#): The location where the metadata about the DRBD device is stored. If you set this to [internal](#), DRBD uses the physical block device to store the information, by recording the metadata within the last sections of the disk. The exact size depends on the size of the logical block device you have created, but it may involve up to 128MB.

A sample configuration for our primary server might look like this:

```
on drbd-one {  
    device /dev/drbd0;  
    disk /dev/hdd1;  
    address 192.168.0.240:8888;  
    meta-disk internal;  
}
```

The `on` configuration block should be repeated for the secondary node (and any further) nodes:

```
on drbd-two {  
  device /dev/drbd0;  
  disk /dev/hdd1;  
  address 192.168.0.241:8888;  
  meta-disk internal;  
}
```

The IP address of each `on` block must match the IP address of the corresponding host. Do not set this value to the IP address of the corresponding primary or secondary in each case.

4. Before starting the primary node, create the metadata for the devices:

```
root-shell> drbdadm create-md all
```

5. You are now ready to start DRBD:

```
root-shell> /etc/init.d/drbd start
```

DRBD should now start and initialize, creating the DRBD devices that you have configured.

6. DRBD creates a standard block device - to make it usable, you must create a file system on the block device just as you would with any standard disk partition. Before you can create the file system, you must mark the new device as the primary device (that is, where the data is written and stored), and initialize the device. Because this is a destructive operation, you must specify the command line option to overwrite the raw data:

```
root-shell> drbdadm -- --overwrite-data-of-peer primary all
```

If you are using a version of DRBD 0.7.x or earlier, then use a different command-line option:

```
root-shell> drbdadm -- --do-what-I-say primary all
```

Now create a file system using your chosen file system type:

```
root-shell> mkfs.ext3 /dev/drbd0
```

7. You can now mount the file system and if necessary copy files to the mount point:

```
root-shell> mkdir /mnt/drbd  
root-shell> mount /dev/drbd0 /mnt/drbd  
root-shell> echo "DRBD Device" >/mnt/drbd/samplefile
```

Your primary node is now ready to use. Next, configure your secondary node or nodes.

#### 14.2.1.4. Setting Up a DRBD Secondary Node

The configuration process for setting up a secondary node is the same as for the primary node, except that you do not have to create the file system on the secondary node device, as this information is automatically transferred from the primary node.

To set up a secondary node:

1. Copy the `/etc/drbd.conf` file from your primary node to your secondary node. It should already contain all the information and configuration that you need, since you had to specify the secondary node IP address and other information for the primary node configuration.
2. Create the DRBD metadata on the underlying disk device:

```
root-shell> drbdadm create-md all
```

3. Start DRBD:

```
root-shell> /etc/init.d/drbd start
```

Once DRBD has started, it starts to copy the data from the primary node to the secondary node. Even with an empty file system this takes some time, since DRBD is copying the block information from a block device, not simply copying the file system data.

You can monitor the progress of the copy between the primary and secondary nodes by viewing the output of `/proc/drbd`:

```
root-shell> cat /proc/drbd
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-one, 2007-07-30 16:43:05
0: cs:SyncSource st:Primary/Secondary ds:UpToDate/Inconsistent C r---
   ns:252284 nr:0 dw:0 dr:257280 al:0 bm:15 lo:0 pe:7 ua:157 ap:0
   [=>.....] sync'ed: 12.3% (1845088/2097152)K
   finish: 0:06:06 speed: 4,972 (4,580) K/sec
   resync: used:1/31 hits:15901 misses:16 starving:0 dirty:0 changed:16
   act_log: used:0/257 hits:0 misses:0 starving:0 dirty:0 changed:0
```

You can monitor the synchronization process by using the `watch` command to run the command at specific intervals:

```
root-shell> watch -n 10 'cat /proc/drbd'
```

### 14.2.1.5. Monitoring a DRBD Device

Once the primary and secondary machines are configured and synchronized, you can get the status information about your DRBD device by viewing the output from `/proc/drbd`:

```
root-shell> cat /proc/drbd
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-one, 2007-07-30 16:43:05
0: cs:Connected st:Primary/Secondary ds:UpToDate/UpToDate C r---
   ns:2175704 nr:0 dw:99192 dr:2076641 al:33 bm:128 lo:0 pe:0 ua:0 ap:0
   resync: used:0/31 hits:134841 misses:135 starving:0 dirty:0 changed:135
   act_log: used:0/257 hits:24765 misses:33 starving:0 dirty:0 changed:33
```

The first line provides the version/revision and build information.

The second line starts the detailed status information for an individual resource. The individual field headings are as follows:

- cs: connection state
- st: node state (local/remote)
- ld: local data consistency
- ds: data consistency
- ns: network send
- nr: network receive
- dw: disk write
- dr: disk read
- pe: pending (waiting for ack)
- ua: unack'd (still need to send ack)
- al: access log write count

In the previous example, the information shown indicates that the nodes are connected, the local node is the primary (because it is listed first), and the local and remote data is up to date with each other. The remainder of the information is statistical data about the device, and the data exchanged that kept the information up to date.

You can also get the status information for DRBD by using the startup script with the `status` option:

```
root-shell> /etc/init.d/drbd status
* status: started
* drbd driver loaded OK; device status: ...
version: 8.3.0 (api:88/proto:86-89)
GIT-hash: 9ba8b93e24d842f0dd3fb1f9b90e8348ddb95829 build by root@gentool.vmbear, 2009-03-14 23:00:06
0: cs:Connected ro:Secondary/Secondary ds:UpToDate/UpToDate C r---
   ns:0 nr:0 dw:0 dr:8385604 al:0 bm:0 lo:0 pe:0 ua:0 ap:0 ep:1 wo:b oos:0
```

The information and statistics are the same.

### 14.2.1.6. Managing a DRBD Installation

For administration, the main command is `drbdadm`. There are a number of commands supported by this tool that control the connectivity and status of the DRBD devices.

#### Note

For convenience, a bash completion script provides tab completion for options to `drbdadm`. The file `drbdadm.bash_completion` can be found within the standard DRBD source package within the `scripts` directory. To enable, copy the file to `/etc/bash_completion.d/drbdadm`. You can load it manually by using:

```
shell> source /etc/bash_completion.d/drbdadm
```

The most common commands are those to set the primary/secondary status of the local device. You can manually set this information for a number of reasons, including to check the physical status of the secondary device (since you cannot mount a DRBD device in primary mode), or when you are temporarily moving the responsibility of keeping the data in check to a different machine (for example, during an upgrade or physical move of the normal primary node). You can set state of all local device to be the primary using this command:

```
root-shell> drbdadm primary all
```

Or switch the local device to be the secondary using:

```
root-shell> drbdadm secondary all
```

To change only a single DRBD resource, specify the resource name instead of `all`.

You can temporarily disconnect the DRBD nodes:

```
root-shell> drbdadm disconnect all
```

Reconnect them using `connect`:

```
root-shell> drbdadm connect all
```

For other commands and help with `drbdadm` see the DRBD documentation.

### 14.2.1.7. Additional DRBD Configuration Options

Additional options you can configure:

- `protocol`: Specifies the level of consistency to be used when information is written to the block device. The option is similar in principle to the `innodb_flush_log_at_trx_commit` option within MySQL. Three levels are supported:
  - **A**: Data is considered written when the information reaches the TCP send buffer and the local physical disk. There is no guarantee that the data has been written to the remote server or the remote physical disk.
  - **B**: Data is considered written when the data has reached the local disk and the remote node's network buffer. The data has reached the remote server, but there is no guarantee it has reached the remote server's physical disk.
  - **C**: Data is considered written when the data has reached the local disk and the remote node's physical disk.

The preferred and recommended protocol is C, as it is the only protocol which ensures the consistency of the local and remote physical storage.

- [size](#): To use less than the entire partition space with your DRBD block device, specify the size of the DRBD device to be created. The size specification can include a quantifier. For example, to set the maximum size of the DRBD partition to 1GB, you would use:

```
size 1G;
```

With the configuration file suitably configured and ready to use, now populate the lower-level device with the metadata information, and then start the DRBD service.

## 14.2.2. Configuring MySQL for DRBD

Once you have configured DRBD and have an active DRBD device and file system, you can configure MySQL to use the chosen device to store the MySQL data.

When performing a new installation of MySQL, you can either select to install MySQL entirely onto the DRBD device, or just configure the data directory to be located on the new file system.

In either case, the files and installation must take place on the primary node, because that is the only DRBD node on which you can mount the DRBD device file system as read/write.

Store the following files and information on your DRBD device:

- MySQL data files, including the binary log, and InnoDB data files.
- MySQL configuration file ([my.cnf](#)).

To set up MySQL to use your new DRBD device and file system:

1. If you are migrating an existing MySQL installation, stop MySQL:

```
shell> mysqladmin shutdown
```

2. Copy the [my.cnf](#) onto the DRBD device. If you are not already using a configuration file, copy one of the sample configuration files from the MySQL distribution.

```
root-shell> mkdir /mnt/drbd/mysql
root-shell> cp /etc/my.cnf /mnt/drbd/mysql
```

3. Copy your MySQL data directory to the DRBD device and mounted file system.

```
root-shell> cp -R /var/lib/mysql /drbd/mysql/data
```

4. Edit the configuration file to reflect the change of directory by setting the value of the [datadir](#) option. If you have not already enabled the binary log, also set the value of the [log-bin](#) option.

```
datadir = /drbd/mysql/data
log-bin = mysql-bin
```

5. Create a symbolic link from [/etc/my.cnf](#) to the new configuration file on the DRBD device file system.

```
root-shell> ln -s /drbd/mysql/my.cnf /etc/my.cnf
```

6. Now start MySQL and check that the data that you copied to the DRBD device file system is present.

```
root-shell> /etc/init.d/mysql start
```

Your MySQL data should now be located on the file system running on your DRBD device. The data is physically stored on the underlying device that you configured for the DRBD device. Meanwhile, the content of your MySQL databases is copied to the secondary DRBD node.

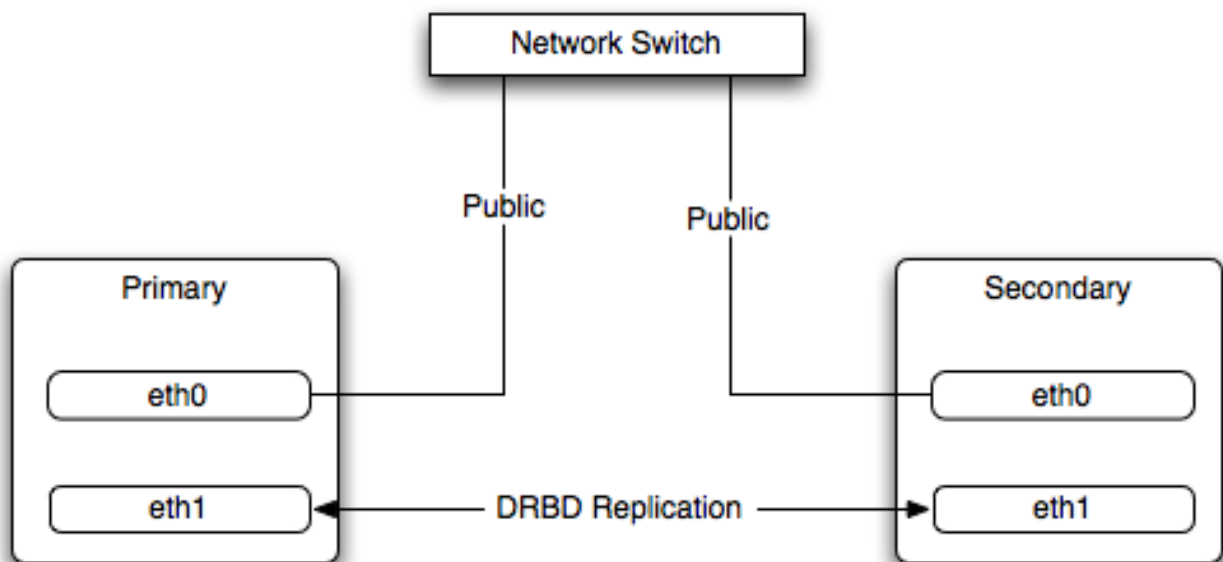

Note that you cannot access the information on your secondary node, as a DRBD device working in secondary mode is not available for use.

### 14.2.3. Optimizing Performance and Reliability

Because of the nature of the DRBD system, the critical requirements are for a very fast exchange of the information between the two hosts. To ensure that your DRBD setup is available to switch over in the event of a failure as quickly as possible, you must transfer the information between the two hosts using the fastest method available.

Typically, a dedicated network circuit should be used for exchanging DRBD data between the two hosts. Use a separate, additional, network interface for your standard network connection. For an example of this layout, see [Figure 14.4, “DRBD Architecture Using Separate Network Interfaces”](#).

**Figure 14.4. DRBD Architecture Using Separate Network Interfaces**

The dedicated DRBD network interfaces should be configured to use a nonrouted TCP/IP network configuration. For example, you might set the primary to use 192.168.0.1 and the secondary 192.168.0.2. These networks and IP addresses should not be part of the normal network subnet.

#### Note

The preferred setup, whenever possible, is to use a direct cable connection (using a crossover cable with Ethernet, for example) between the two machines. This eliminates the risk of loss of connectivity due to switch failures.

#### 14.2.3.1. Using Bonded Ethernet Network Interfaces

For a set-up where there is a high-throughput of information being written, consider using bonded network interfaces. This is where you combine the connectivity of more than one network port, increasing the throughput linearly according to the number of bonded connections.

Bonding also provides an additional benefit in that with multiple network interfaces effectively supporting the same communications channel, a fault within a single network interface in a bonded group does not stop communication. For example, imagine you have a bonded setup with four network interfaces providing a single interface channel between two DRBD servers. If one network interface

fails, communication can continue on the other three without interruption, although at a lower speed.

To enable bonded connections you must enable bonding within the kernel. Then configure the module to specify the bonded devices and then configure each new bonded device just as you would a standard network device:

- To configure the bonded devices, edit the `/etc/modprobe.conf` file (Red Hat) or add a file to the `/etc/modprobe.d` directory. In each case, you define the parameters for the kernel module. First, specify each bonding device:

```
alias bond0 bonding
```

You can then configure additional parameters for the kernel module. Typical parameters are the `mode` option and the `miimon` option.

The `mode` option specifies how the network interfaces are used. The default setting is 0, which means that each network interface is used in a round-robin fashion (this supports aggregation and fault tolerance). Using setting 1 sets the bonding mode to active-backup. This means that only one network interface is used as a time, but that the link automatically fails over to a new interface if the primary interface fails. This settings only supports fault-tolerance.

The `miimon` option enables the MII link monitoring. A positive value greater than zero indicates the monitoring frequency in milliseconds for checking each slave network interface that is configured as part of the bonded interface. A typical value is 100.

You set the options within the module parameter file, and you must set the options for each bonded device individually:

```
options bond0 miimon=100 mode=1
```

- Reboot your server to enable the bonded devices.
- Configure the network device parameters. This is a two-part process: set up the bonded device configuration, then configure the original network interfaces as 'slaves' of the new bonded interface.
- For Red Hat Linux:

Edit the configuration file for the bonded device. For device `bond0`, this would be `/etc/sysconfig/network-scripts/ifcfg-bond0`:

```
DEVICE=bond0
BOOTPROTO=none
ONBOOT=yes
GATEWAY=192.168.0.254
NETWORK=192.168.0.0
NETMASK=255.255.255.0
IPADDR=192.168.0.1
USERCTL=no
```

Then for each network interface to be part of the bonded device, configure the interface as a slave to the 'master' bond. For example, the configuration of `eth0` in `/etc/sysconfig/network-scripts/ifcfg-eth0` might look like this::

```
DEVICE=eth0
BOOTPROTO=none
HWADDR=00:11:22:33:44:55
ONBOOT=yes
TYPE=Ethernet
MASTER=bond0
SLAVE=yes
```

- For Debian Linux:

Edit the `/etc/iftab` file and configure the logical name and MAC address for each device. For example:

```
eth0 mac 00:11:22:33:44:55
```

Now set the configuration of the devices in `/etc/network/interfaces`:

```
auto bond0
iface bond0 inet static
address 192.168.0.1
netmask 255.255.255.0
network 192.168.0.0
```

```
gateway 192.168.0.254
up /sbin/ifenslave bond0 eth0
up /sbin/ifenslave bond0 eth1
```

- For Gentoo:

Use `emerge` to add the `net-misc/ifenslave` package to your system.

Edit the `/etc/conf.d/net` file and specify the network interface slaves in a bond, the dependencies and then the configuration for the bond itself. A sample configuration might look like this:

```
slaves_bond0="eth0 eth1 eth2"
config_bond0=( "192.168.0.1 netmask 255.255.255.0" )
depend_bond0() {
    need net.eth0 net.eth1 net.eth2
}
```

Then make sure that you add the new network interface to list of interfaces configured during boot:

```
root-shell> rc-update add default net.bond0
```

Once the bonded devices are configured, reboot your systems.

You can monitor the status of a bonded connection using the `/proc` file system:

```
root-shell> cat /proc/net/bonding/bond0
Bonding Mode: fault-tolerance (active-backup)
Primary Slave: None
Currently Active Slave: eth1
MII Status: up
MII Polling Interval (ms): 100
Up Delay (ms): 200
Down Delay (ms): 200
Slave Interface: eth1
MII Status: up
Link Failure Count: 0
Permanent HW addr: 00:11:22:33:44:55
Slave Interface: eth2
MII Status: up
Link Failure Count: 0
Permanent HW addr: 00:11:22:33:44:56
```

### 14.2.3.2. Optimizing the Synchronization Rate

The `syncer rate` configuration parameter should be configured with care as the synchronization rate can have a significant effect on the performance of the DRBD setup in the event of a node or disk failure where the information is being synchronized from the Primary to the Secondary node.

In DRBD, there are two distinct ways of data being transferred between peer nodes:

- *Replication* refers to the transfer of modified blocks being transferred from the primary to the secondary node. This happens automatically when the block is modified on the primary node, and the replication process uses whatever bandwidth is available over the replication link. The replication process cannot be throttled, because you want transfer of the block information to happen as quickly as possible during normal operation.
- *Synchronization* refers to the process of bringing peers back in sync after some sort of outage, due to manual intervention, node failure, disk swap, or the initial setup. Synchronization is limited to the `syncer rate` configured for the DRBD device.

Both replication and synchronization can take place at the same time. For example, the block devices can be synchronized while they are actively being used by the primary node. Any I/O that updates on the primary node automatically triggers replication of the modified block. In the event of a failure within an HA environment, it is highly likely that synchronization and replication will take place at the same time.

Unfortunately, if the synchronization rate is set too high, then the synchronization process uses up all the available network bandwidth between the primary and secondary nodes. In turn, the bandwidth available for replication of changed blocks is zero, which stalls replication and blocks I/O, and ultimately the application fails or degrades.

To avoid enabling the `syncer rate` to consume the available network bandwidth and prevent the replication of changed blocks, set the `syncer rate` to less than the maximum network bandwidth.

Avoid setting the sync rate to more than 30% of the maximum bandwidth available to your device and network bandwidth. For example, if your network bandwidth is based on Gigabit ethernet, you should achieve 110MB/s. Assuming your disk interface is capable of handling data at 110MB/s or more, then the sync rate should be configured as `33M` (33MB/s). If your disk system works at a rate lower than your network interface, use 30% of your disk interface speed.

Depending on the application, you might limit the synchronization rate. For example, on a busy server you could configure a significantly slower synchronization rate to ensure the replication rate is not affected.

The `al-extents` parameter controls the number of 4MB blocks of the underlying disk that can be written to at the same time. Increasing this parameter lowers the frequency of the metadata transactions required to log the changes to the DRBD device, which in turn lowers the number of interruptions in your I/O stream when synchronizing changes. This can lower the latency of changes to the DRBD device. However, if a crash occurs on your primary, then all of the blocks in the activity log (that is, the number of `al-extents` blocks) must be completely resynchronized before replication can continue.

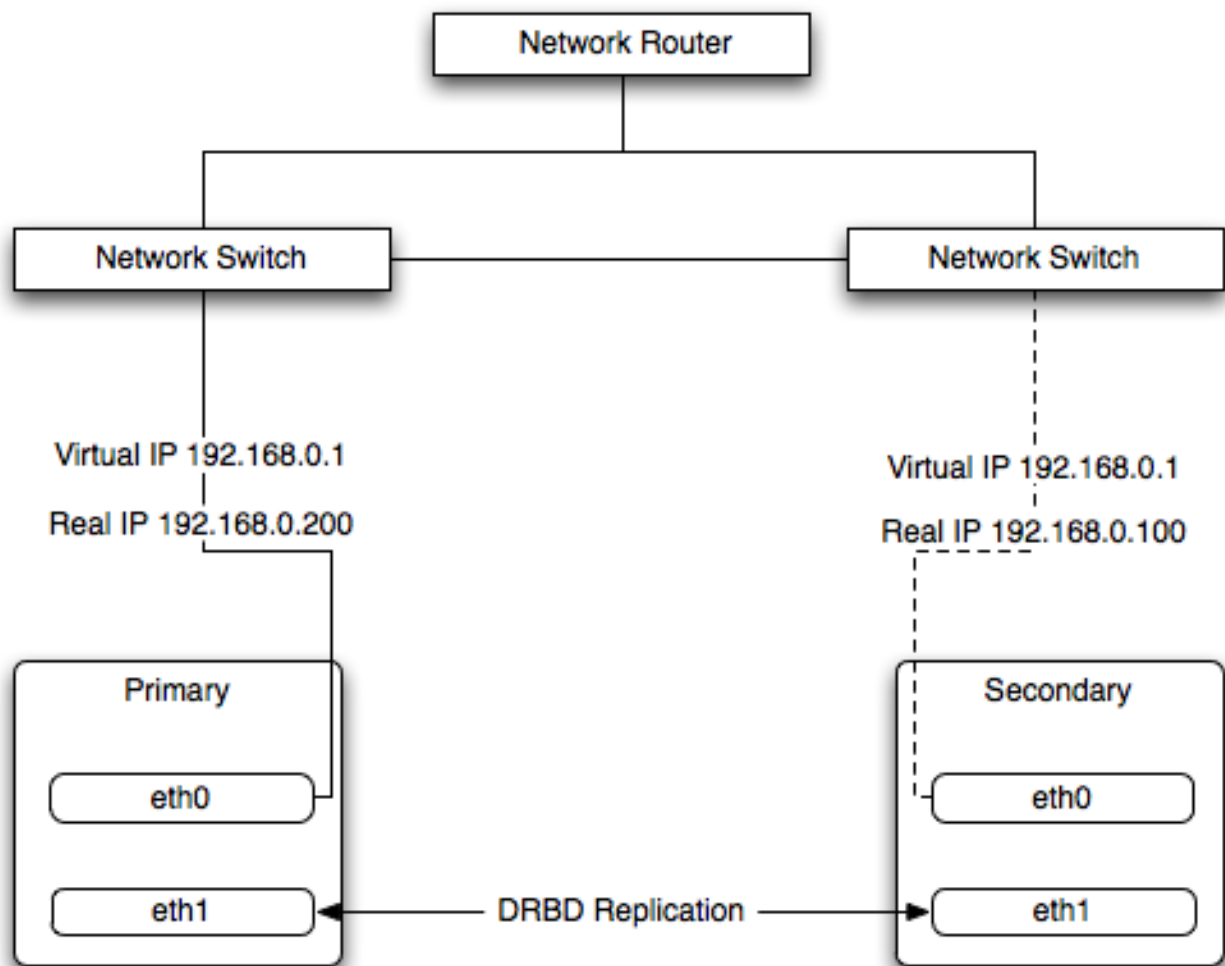

## 14.3. Using Linux HA Heartbeat

The Heartbeat program provides a basis for verifying the availability of resources on one or more systems within a cluster. In this context a resource includes MySQL, the file systems on which the MySQL data is being stored and, if you are using DRBD, the DRBD device being used for the file system. Heartbeat also manages a virtual IP address; use this virtual IP address for all communication to the MySQL instance.

A cluster within the context of Heartbeat is defined as two computers notionally providing the same service. By definition, each computer in the cluster is physically capable of providing the same services as all the others in the cluster. However, because the cluster is designed for high-availability, only one of the servers is actively providing the service at any one time. Each additional server within the cluster is a “hot-spare” that can be brought into service in the event of a failure of the master, its next connectivity or the connectivity of the network in general.

The basics of Heartbeat are very simple. Within the Heartbeat cluster (see [Figure 14.5, “Heartbeat Architecture”](#)), each machine sends a ‘heartbeat’ signal to the other hosts in the cluster. The other cluster nodes monitor this heartbeat. The heartbeat can be transmitted over many different systems, including shared network devices, dedicated network interfaces and serial connections. Failure to get a heartbeat from a node is treated as failure of the node. Although we do not know the reason for the failure (it could be an OS failure, a hardware failure in the server, or a failure in the network switch), it is safe to assume that if no heartbeat is produced there is a fault.

**Figure 14.5. Heartbeat Architecture**

In addition to checking the heartbeat from the server, the system can also check the connectivity (using [ping](#)) to another host on the network, such as the network router. This enables Heartbeat to detect a failure of communication between a server and the router (and therefore failure of the server, since it is no longer capable of providing the necessary service), even if the heartbeat between the servers in the clusters is working fine.

In the event of a failure, the resources on the failed host are disabled, and the resources on one of the replacement hosts is enabled instead. In addition, the Virtual IP address for the cluster is redirected to the new host in place of the failed device.

When used with MySQL and DRBD, the MySQL data is replicated from the master to the slave using the DRBD device, but MySQL is only running on the master. When the master fails, the slave switches the DRBD devices to be primary, the file systems on those devices are mounted, and MySQL is started. The original master (if still available) has its resources disabled, which means shutting down MySQL and unmounting the file systems and switching the DRBD device to secondary.

### 14.3.1. Heartbeat Configuration

Heartbeat configuration requires three files located in `/etc/ha.d`. The `ha.cf` contains the main heartbeat configuration, including the list of the nodes and times for identifying failures. `haresources` contains the list of resources to be managed within the cluster. The `authkeys` file contains the security information for the cluster.

The contents of these files should be identical on each host within the Heartbeat cluster. It is important that you keep these files in sync across all the hosts. Any changes in the information on one host should be copied to the all the others.

For these examples an example of the `ha.cf` file is shown below:

```
logfacility local0
keepalive 500ms
deadtime 10
warntime 5
initdead 30
mcast bond0 225.0.0.1 694 2 0
mcast bond1 225.0.0.2 694 1 0
auto_failback off
node drbd1
node drbd2
```

The individual lines in the file can be identified as follows:

- **logfacility**: Sets the logging, in this case setting the logging to use **syslog**.
- **keepalive**: Defines how frequently the heartbeat signal is sent to the other hosts.
- **deadtime**— the delay in seconds before other hosts in the cluster are considered 'dead' (failed).
- **warntime**: The delay in seconds before a warning is written to the log that a node cannot be contacted.
- **initdead**: The period in seconds to wait during system startup before the other host is considered to be down.
- **mcast**: Defines a method for sending a heartbeat signal. In the above example, a multicast network address is being used over a bonded network device. If you have multiple clusters then the multicast address for each cluster should be unique on your network. Other choices for the heartbeat exchange exist, including a serial connection.

If you are using multiple network interfaces (for example, one interface for your server connectivity and a secondary or bonded interface for your DRBD data exchange), use both interfaces for your heartbeat connection. This decreases the chance of a transient failure causing an invalid failure event.

- **auto\_failback**: Sets whether the original (preferred) server should be enabled again if it becomes available. Switching this to **on** may cause problems if the preferred went offline and then comes back on line again. If the DRBD device has not been synced properly, or if the problem with the original server happens again you may end up with two different datasets on the two servers, or with a continually changing environment where the two servers flip-flop as the preferred server reboots and then starts again.
- **node**: Sets the nodes within the Heartbeat cluster group. There should be one **node** for each server.

An optional additional set of information provides the configuration for a ping test that checks the connectivity to another host. Use this to ensure that you have connectivity on the public interface for your servers, so the ping test should be to a reliable host such as a router or switch. The additional lines specify the destination machine for the **ping**, which should be specified as an IP address, rather than a host name; the command to run when a failure occurs, the authority for the failure and the timeout before a nonresponse triggers a failure. A sample configuration is shown below:

```
ping 10.0.0.1
respawn hacluster /usr/lib64/heartbeat/ipfail
apiauth ipfail gid=haclient uid=hacluster
deadping 5
```

In the above example, the **ipfail** command, which is part of the Heartbeat solution, is called on a failure and 'fakes' a fault on the currently active server. Configure the user and group ID under which the command is executed (using the **apiauth**). The failure is triggered after 5 seconds.

### Note

The **deadping** value must be less than the **deadtime** value.

The **authkeys** file holds the authorization information for the Heartbeat cluster. The authorization relies on a single unique 'key' that is used to verify the two machines in the Heartbeat cluster. The file is used only to confirm that the two machines are in the same cluster and is used to ensure that the multiple clusters can co-exist within the same network.

## 14.3.2. Using Heartbeat with MySQL and DRBD

To use Heartbeat in combination with MySQL, use DRBD (see [Section 14.2, “Using MySQL with DRBD”](#)) or another solution that enables sharing the MySQL database files in event of a system failure. In these examples, DRBD is used as the data sharing solution.

Heartbeat manages the configuration of different resources to manage the switching between two servers in the event of a failure. The resource configuration defines the individual services that should be brought up (or taken down) in the event of a failure.

The `haresources` file within `/etc/ha.d` defines the resources that should be managed, and the individual resource mentioned in this file in turn relates to scripts located within `/etc/ha.d/resource.d`. The resource definition is defined all on one line:

```
drbd1 drbddisk Filesystem::/dev/drbd0::/drbd::ext3 mysql 10.0.0.100
```

The line is notionally split by whitespace. The first entry (`drbd1`) is the name of the preferred host; that is the server that is normally responsible for handling the service. The last field is virtual IP address or name that should be used to share the service. This is the IP address that should be used to connect to the MySQL server. It is automatically allocated to the server that is active when Heartbeat starts.

The remaining fields between these two fields define the resources that should be managed. Each Field should contain the name of the resource (and each name should refer to a script within `/etc/ha.d/resource.d`). In the event of a failure, these resources are started on the backup server by calling the corresponding script (with a single argument, `start`), in order from left to right. If there are additional arguments to the script, you can use a double colon to separate each additional argument.

In the above example, we manage the following resources:

- **drbddisk**: The DRBD resource script, this switches the DRBD disk on the secondary host into primary mode, making the device read/write.
- **Filesystem**: Manages the Filesystem resource. In this case we have supplied additional arguments to specify the DRBD device, mount point and file system type. When executed this should mount the specified file system.
- **mysql**: Manages the MySQL instances and starts the MySQL server. Copy the `mysql.resource` file from the `support-files` directory from any MySQL release into the `/etc/ha.d/resources.d` directory.

If this file is not available in your distribution, you can use the following as the contents of the `/etc/ha.d/resource.d/mysql.resource` file:

```
#!/bin/bash
#
# This script is intended to be used as resource script by heartbeat
#
# Mar 2006 by Monty Taylor
#
###

. /etc/ha.d/shellfuncs

case "$1" in
    start)
        res=`/etc/init.d/mysql start`
        ret=$?
        ha_log $res
        exit $ret
        ;;
    stop)
        res=`/etc/init.d/mysql stop`
        ret=$?
        ha_log $res
        exit $ret
        ;;
    status)
        if [[ `ps -ef | grep '[mysqld]' > 1` ]] ; then
            echo "running"
        else
            echo "stopped"
        fi
        ;;
    *)
        echo "Usage: mysql {start|stop|status}"
        exit 1
        ;;
esac

exit 0
```

To be notified of the failure by email, add another line to the `haresources` file with the address for warnings and the warning text:

```
MailTo::youremail@address.com::DRBDFailure
```

With the Heartbeat configuration in place, copy the `haresources`, `authkeys` and `ha.cf` files from your primary and secondary servers to make sure that the configuration is identical. Then start the Heartbeat service, either by calling `/etc/init.d/heartbeat start` or by rebooting both primary and secondary servers.

You can test the configuration by running a manual failover, connect to the primary node and run:

```
root-shell> /usr/lib64/heartbeat/hb_standby
```

This causes the current node to relinquish its resources cleanly to the other node.

### 14.3.3. Using Heartbeat with DRBD and `dopd`

As a further extension to using DRBD and Heartbeat together, you can enable `dopd`. The `dopd` daemon handles the situation where a DRBD node is out of date compared to the master and prevents the slave from being promoted to master in the event of a failure. This stops a situation where you have two machines that have been masters ending up different data on the underlying device.

For example, imagine that you have a two server DRBD setup, master and slave. If the DRBD connectivity between master and slave fails, then the slave is out of the sync with the master. If Heartbeat identifies a connectivity issue for master and then switches over to the slave, the slave DRBD device is promoted to the primary device, even though the data on the slave and the master is not in synchronization.

In this situation, with `dopd` enabled, the connectivity failure between the master and slave would be identified and the metadata on the slave would be set to `Outdated`. Heartbeat refuses to switch over to the slave even if the master failed. In a dual-host solution this would effectively render the cluster out of action, as there is no additional fail over server. In an HA cluster with three or more servers, control would be passed to the slave that has an up to date version of the DRBD device data.

To enable `dopd`, modify the Heartbeat configuration and specify `dopd` as part of the commands executed during the monitoring process. Add the following lines to your `ha.cf` file:

```
respawn hacluster /usr/lib/heartbeat/dopd
apiauth dopd gid=haclient uid=hacluster
```

Make sure you make the same modification on both your primary and secondary nodes.

Reload the Heartbeat configuration:

```
root-shell> /etc/init.d/heartbeat reload
```

Modify your DRBD configuration by configuration the `outdate-peer` option. Add the configuration line into the `common` section of `/etc/drbd.conf` on both hosts. An example of the full block is shown below:

```
common {
  handlers {
    outdate-peer "/usr/lib/heartbeat/drbd-peer-outdater";
  }
}
```

Finally, set the `fencing` option on your DRBD configured resources:

```
resource my-resource {
  disk {
    fencing    resource-only;
  }
}
```

Now reload your DRBD configuration:

```
root-shell> drbdadmin adjust all
```

You can test the system by unplugging your DRBD link and monitoring the output from `/proc/drbd`.

### 14.3.4. Dealing with System Level Errors

Because a kernel panic or oops may indicate potential problem with your server, configure your server to remove itself from the cluster in the event of a problem. Typically on a kernel panic, your system automatically triggers a hard reboot. For a kernel oops, a reboot may not happen automatically, but the issue that caused that oops may still lead to potential problems.

You can force a reboot by setting the `kernel.panic` and `kernel.panic_on_oops` parameters of the kernel control file `/etc/sysctl.conf`. For example:

```
kernel.panic_on_oops = 1
kernel.panic = 1
```

You can also set these parameters during runtime by using the `sysctl` command. You can either specify the parameters on the command line:

```
shell> sysctl -w kernel.panic=1
```

Or you can edit your `sysctl.conf` file and then reload the configuration information:

```
shell> sysctl -p
```

Setting both these parameters to a positive value (representing the number of seconds to wait before rebooting), causes the system to reboot. Your second heartbeat node should then detect that the server is down and then switch over to the failover host.

## 14.4. Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, enabling you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you intend to use, and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL services and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as `m1.small`), large (`m1.large`) and extra large (`m1.xlarge`). The different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown here.

	Small	Large	Extra Large
Platform	32-bit	64-bit	64-bit
CPU cores	1	2	4
ECUs	1	4	8
RAM	1.7GB	7.5GB	15GB
Storage	150GB	840GB	1680GB
I/O Performance	Medium	High	High

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to

port and migrate your data to the running instance, see [Section 14.4.1, “Setting Up MySQL on an EC2 AMI”](#).

For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see [Section 14.4.3, “Deploying a MySQL Database Using EC2”](#).

## 14.4.1. Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default *Getting Started* AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using `yum`:

```
shell> yum install mysql
```

This installs both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL Web site. The installation process and instructions are identical to any other installation of MySQL on Linux. See [Chapter 2, \*Installing and Upgrading MySQL\*](#).

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` option to point to the larger storage area.

### Important

The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.

To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding creates a 50GB on the file system and starts the initialization process. Delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization takes between two and three hours. For the large and extra large drives, the initialization can be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, also consider setting the following other settings in your instance before you save the instance configuration for deployment:

- Set the MySQL server ID, so that when you use it for replication, the ID information is set correctly.
- Enabling binary logging, so that replication can be initialized without starting and stopping the server.
- Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install `memcached` on the servers as part of your application stack you must ensure there is enough memory for both MySQL and `memcached`.

Once you have configured your AMI with MySQL and the rest of your application stack, save the AMI so that you can deploy and re-use the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using `mysqldump`, transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation, be aware of the limitations of the EC2 instance environment. See [Section 14.4.2, “EC2 Instance Limitations”](#). To begin using your MySQL AMI, consult the notes on deployment. See [Section 14.4.3, “Deploying a MySQL Database Using EC2”](#).

## 14.4.2. EC2 Instance Limitations

Be aware of the following limitations of the EC2 instances before deploying your applications. Although these shouldn't affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

- Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data only remains in place while the machine is running, and does not survive a reboot. If you shut down the instance, any data it contained is lost.

To ensure that you do not lose information, take regular backups using `mysqldump`. If the data being stored is critical, consider using replication to keep a “live” backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

- EC2 instances are not persistent. If the hardware on which an instance is running fails, the instance is shut down. This can lead to loss of data or service.
- To replicate your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.
- Certain HA features are either not directly supported, or have limiting factors or problems that could reduce their utility. For example, using DRBD or MySQL Cluster might not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

## 14.4.3. Deploying a MySQL Database Using EC2

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment, use an approach that enables you to easily distribute work among your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.

The EC2 architecture works best when you treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, take advantage of other services, such as `memcached` to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can provide a large memory cache for data.

Most types of scale-out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, be prepared to alter your application to use sharding and add further EC2 instances to improve the performance of your application.

For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.

You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

**Note**

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. Always use these internal addresses and names when communicating between instances. Only use public IP addresses when communicating with the outside world - for example, when publicizing your application.

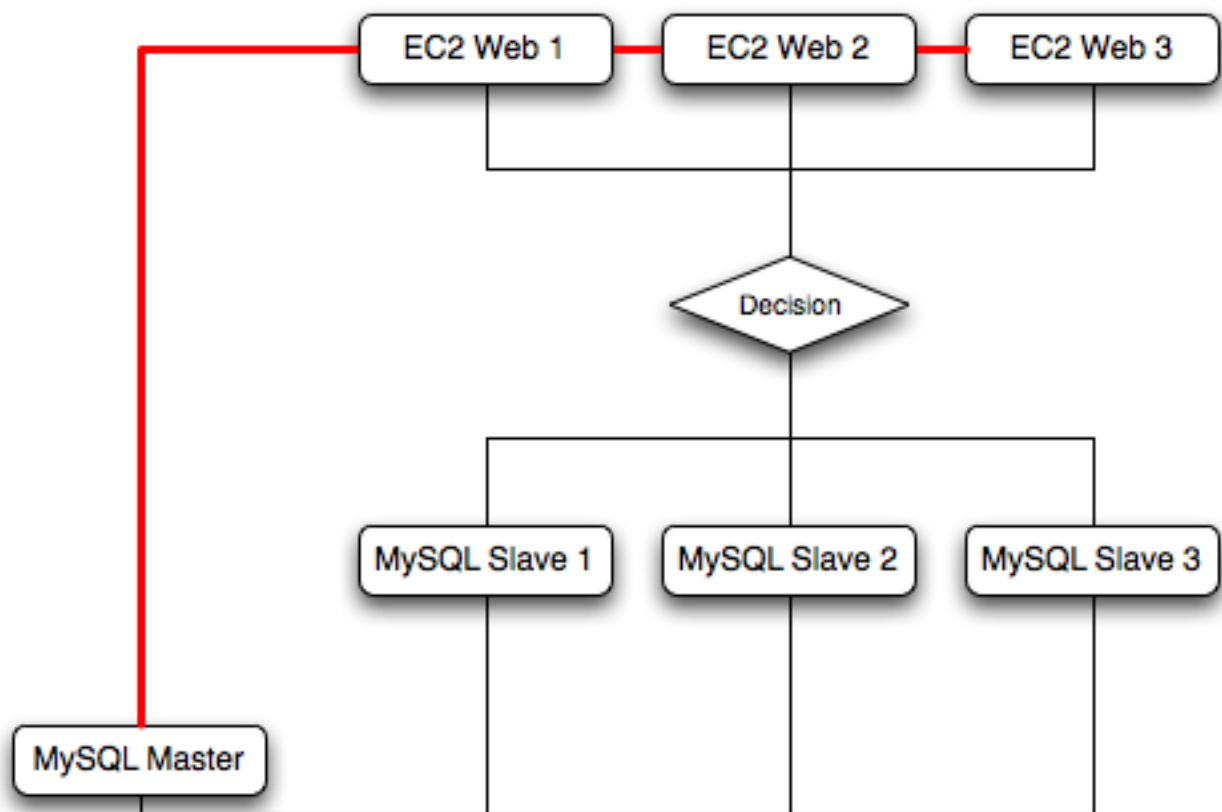

To ensure reliability of your database, add at least one replication slave dedicated to providing an active backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.

Using [memcached](#) within your EC2 instances should provide better performance. The large and extra large instances have a significant amount of RAM. To use [memcached](#) in your application, when loading information from the database, first check whether the item exists in the cache. If the data you are looking for exists in the cache, use it. If not, reload the data from the database and populate the cache.

**Sharding** divides up data in your entire database by allocating individual machines or machine groups to provide a unique set of data according to an appropriate group. For example, you might put all users with a surname ending in the letters A-D onto a single server. When a user connects to the application and their surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2, separate the web server and MySQL server into separate EC2 instances, and then apply the sharding decision logic into your application. Once you know which MySQL server you should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.

**Warning**

With sharding and EC2, be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard becomes unavailable.

## 14.5. Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, including [Chapter 15, Replication](#) and [Section 14.2, “Using MySQL with DRBD”](#).

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

Filesystem	size	used	avail	capacity	Mounted on
/dev/dsk/c0d0s0	4.6G	3.7G	886M	82%	/
/devices	0K	0K	0K	0%	/devices
ctfs	0K	0K	0K	0%	/system/contract
proc	0K	0K	0K	0%	/proc
mnttab	0K	0K	0K	0%	/etc/mnttab
swap	1.4G	892K	1.4G	1%	/etc/svc/volatile
objfs	0K	0K	0K	0%	/system/object
/usr/lib/libc/libc_hwcapi.so.1	4.6G	3.7G	886M	82%	/lib/libc.so.1
fd	0K	0K	0K	0%	/dev/fd
swap	1.4G	40K	1.4G	1%	/tmp
swap	1.4G	28K	1.4G	1%	/var/run
/dev/dsk/c0d0s7	26G	913M	25G	4%	/export/home
scratchpool	16G	24K	16G	1%	/scratchpool

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x  31 root    bin          50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root    bin           5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root    sys          16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000   1000         40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1    0      -    24.5K  -
scratchpool@snap2    0      -    24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

### 14.5.1. Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x  6 root    root      7 Nov  8 09:13 ./
drwxr-xr-x 29 root    root      34 Nov  9 07:06 ../
drwxr-xr-x 31 root    bin       50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root    bin       5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root    sys       16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000   1000     40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

## 14.5.2. Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send`/ `zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals. For automated operations, see [Tim Foster's zfs replication tool](#).

## 14.5.3. Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or auto-

matically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On `MyISAM` tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

## 14.6. Using MySQL with `memcached`

`memcached` is a simple, yet highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for very quick access by applications, without going through layers of parsing or disk I/O. To use, you run `memcached` on one or more hosts and then use the shared cache to store objects. Because each host's RAM is storing information, the access speed is much faster than loading the information from disk. This can provide a significant performance boost in retrieving data versus loading the data natively from a database. Also, because the cache is just a repository for information, you can use the cache to store any data, including complex structures that would normally require a significant amount of effort to create, but in a ready-to-use format, helping to reduce the load on your MySQL servers.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information isn't in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 14.6, “memcached Architecture Overview”](#).

**Figure 14.6.** `memcached` Architecture Overview

In the example structure, any of the clients can contact one of the **memcached** servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the **memcached** servers. The selection of the **memcached** server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same **memcached** server is selected as the source for the data. Using this method, the cached data is spread among all of the **memcached** servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional **memcached** server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a **memcached** server fails, the data can always be recovered from the MySQL database.

## memcached Integration with MySQL Storage Engines

In April 2011, MySQL announced the preview of a new memcached interface for the InnoDB and MySQL Cluster storage engines.

Using the memcached API, web services can directly access the InnoDB and MySQL Cluster storage engines without transformations to SQL, ensuring low latency and high throughput for read/write queries. Operations such as SQL parsing are eliminated and more of the server's hardware resources (CPU, memory and I/O) are dedicated to servicing the query within the storage engine itself. The **memcached** data can be persisted to disk while still cached in memory for fast retrieval.

These are targeted to be incorporated into future MySQL 5.6 Milestone and MySQL Cluster Development Releases.

You can learn more about these interfaces from this Dev Zone article: <http://dev.mysql.com/tech-resources/articles/nosql-to-mysql-with-memcached.html>.

### 14.6.1. Installing memcached

You can build and install **memcached** from the source code directly, or you can use an existing operating system package or installation.

#### Installing memcached from a Binary Distribution

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

### Note

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

### Building `memcached` from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and Mac OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached Web site](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you might specify to the `configure`:

- `--prefix`

To specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support.

For more information on the threading support, see [Section 14.6.2.7, “memcached thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 14.6.2.5, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

## 14.6.2. Using `memcached`

To start using `memcached`, you must start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

### Note

You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in

megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

### Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
kthr    memory           page            disk           faults          cpu
r  b  w    swap  free  re  mf  pi  po  fr  de  sr  sl  s2  --  --    in    sy    cs  us  sy  id
0  0  0  5170504 3450392 2   7   2   0   0   0   4   0   0   0   0   296   54   199   0   0  100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

### Note

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- `-s socket`

Specify a Unix socket to listen on.

If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local UNIX socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a UNIX socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

Specify the number of threads to use when processing incoming requests.

By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

### Note

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

Print the help message and exit.

- `-i`

Print the `memcached` and `libevent` license.

- `-I mem`

Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- `-b`

Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

Save the process ID of the `memcached` instance into `file`.

- `-f`

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see [Section 14.6.2.8, “memcached Logs”](#).

- `-n bytes`

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

Disable the use of compare and swap (CAS) operations.

This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see [Section 14.6.4, “Getting memcached Statistics”](#)). The default is the colon (`:`). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in [memcached 1.4.0](#).

### 14.6.2.1. [memcached](#) Deployment

When using [memcached](#) you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying [memcached](#) within your system, keep in mind the following points:

- [memcached](#) is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the [memcached](#) protocol. At a minimum, make sure that the servers running [memcached](#) are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the [memcached](#) servers that is being stored is any sensitive, then encrypt the information before storing it in [memcached](#).
- [memcached](#) does not provide any sort of failover. Because there is no communication between different [memcached](#) instances. If an instance fails, your application must be capable of removing it from the list, reloading the data and then writing data to another [memcached](#) instance.
- Latency between the clients and the [memcached](#) can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the [memcached](#) instances to be on the clients.
- Key length is determined by the [memcached](#) server. The default maximum key size is 250 bytes.
- Using a single [memcached](#) instance, especially for multiple clients, is generally a bad idea as it introduces a single point of failure. Instead provide at least two [memcached](#) instances so that a failure can be handled appropriately. If possible, you should create as many [memcached](#) nodes as possible. When adding and removing [memcached](#) instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 14.6.2.4, “memcached Hashing/Distribution Types”](#).

### 14.6.2.2. Using namespaces

The [memcached](#) cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieved from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

#### Note

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within [memcached](#), and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

### 14.6.2.3. Data Expiry

There are two types of data expiry within a [memcached](#) instance. The first type is applied at the point when you store a new key/value pair into the [memcached](#) instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to [memcached](#) is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 14.6.4, “Getting memcached Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting [memcached](#). This option forces an error

to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. [memcached](#) uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

#### 14.6.2.4. [memcached](#) Hashing/Distribution Types

The [memcached](#) client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given [memcached](#) instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within [memcache](#) clients uses a simple modulus calculation on the value against the number of configured [memcached](#) servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 ( $7009 \% 3 = 1$ ), and store or retrieve the key and value with that server.

#### Note

This selection and hashing process is handled automatically by the [memcached](#) client you are using; you need only provide the list of [memcached](#) servers to use.

You can see a graphical representation of this below in [Figure 14.7, “memcached Hash Selection”](#).

**Figure 14.7.** [memcached](#) Hash Selection

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).
- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

#### Note

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

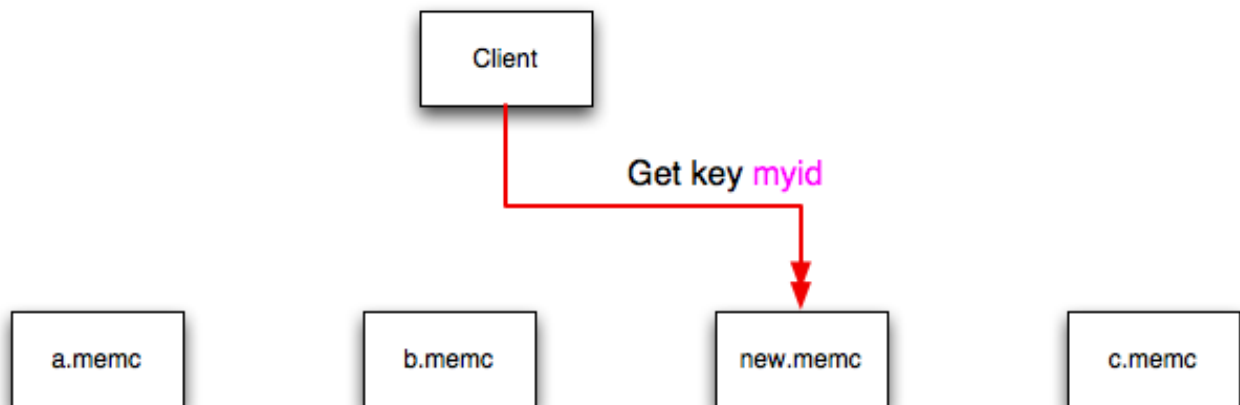

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

- A new `memcached` instance has been added to the list of available instances
- A `memcached` instance has been removed from the list of available instances
- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

**Figure 14.8. `memcached` Hash Selection with New `memcached` instance**

This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

#### 14.6.2.5. Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, Mac OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see [Section 14.6.1, “Installing memcached”](#).

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid`: The connection ID

- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid`: The connection ID

- `conn-create(ptr)`

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:

- `ptr`: A pointer to the connection object

- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr`: A pointer to the connection object

- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid`: The connection ID

- `threadid`: The thread ID

- `slabs-allocate(size, slabclass, slabsize, ptr)`

Allocate memory from the slab allocator

Arguments:

- `size`: The requested size

- `slabclass`: The allocation is fulfilled in this class

- `slabsize`: The size of each item in this class

- `ptr`: A pointer to allocated memory

- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory)

Arguments:

- `size`: The requested size
- `slabclass`: The class that failed to fulfill the request

- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space

Arguments:

- `slabclass`: The class that needs more memory

- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory)

Arguments:

- `slabclass`: The class that failed to grab more memory

- `slabs-free(size, slabclass, ptr)`

Release memory

Arguments:

- `size`: The size of the memory
- `slabclass`: The class the memory belongs to
- `ptr`: A pointer to the memory to release

- `assoc-find(key, depth)`

Fired when the when we have searched the hash table for a named key. These two elements provide an insight in how well the hash function operates. Traversals are a sign of a less optimal function, wasting cpu capacity.

Arguments:

- `key`: The key searched for
- `depth`: The depth in the list of hash table

- `assoc-insert(key, nokeys)`

Fired when a new item has been inserted.

Arguments:

- `key`: The key just inserted
- `nokeys`: The total number of keys currently being stored, including the key for which insert was called.

- `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key`: The key just deleted

- `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.

- `item-link(key, size)`

Fired when an item is being linked in the cache

Arguments:

- `key`: The items key
- `size`: The size of the data

- `item-unlink(key, size)`

Fired when an item is being deleted

Arguments:

- `key`: The items key
- `size`: The size of the data

- `item-remove(key, size)`

Fired when the refcount for an item is reduced

Arguments:

- `key`: The items key
- `size`: The size of the data

- `item-update(key, size)`

Fired when the "last referenced" time is updated

Arguments:

- `key`: The items key
- `size`: The size of the data

- `item-replace(oldkey, oldsize, newkey, newsize)`

Fired when an item is being replaced with another item

Arguments:

- `oldkey`: The key of the item to replace
- `oldsize`: The size of the old item
- `newkey`: The key of the new item
- `newsize`: The size of the new item

- `process-command-start(connid, request, size)`

Fired when the processing of a command starts

Arguments:

- `connid`: The connection ID
- `request`: The incoming request

- `size`: The size of the request

- `process-command-end(connid, response, size)`

Fired when the processing of a command is done

Arguments:

- `connid`: The connection ID
- `response`: The response to send back to the client
- `size`: The size of the response

- `command-get(connid, key, size)`

Fired for a get-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The size of the key's data (or -1 if not found)

- `command-gets(connid, key, size, casid)`

Fired for a gets command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The size of the key's data (or -1 if not found)
- `casid`: The casid for the item

- `command-add(connid, key, size)`

Fired for a add-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)

- `command-set(connid, key, size)`

Fired for a set-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)

- `command-replace(connid, key, size)`

Fired for a replace-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-prepend(connid, key, size)`

Fired for a prepend-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-append(connid, key, size)`

Fired for a append-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-cas(connid, key, size, casid)`

Fired for a cas-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The size of the key's data (or -1 if not found)
- `casid`: The cas ID requested
- `command-incr(connid, key, val)`

Fired for incr command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `val`: The new value
- `command-decr(connid, key, val)`

Fired for decr command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `val`: The new value
- `command-delete(connid, key, exptime)`

Fired for a delete command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `exptime`: The expiry time

#### 14.6.2.6. Memory allocation within `memcached`

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

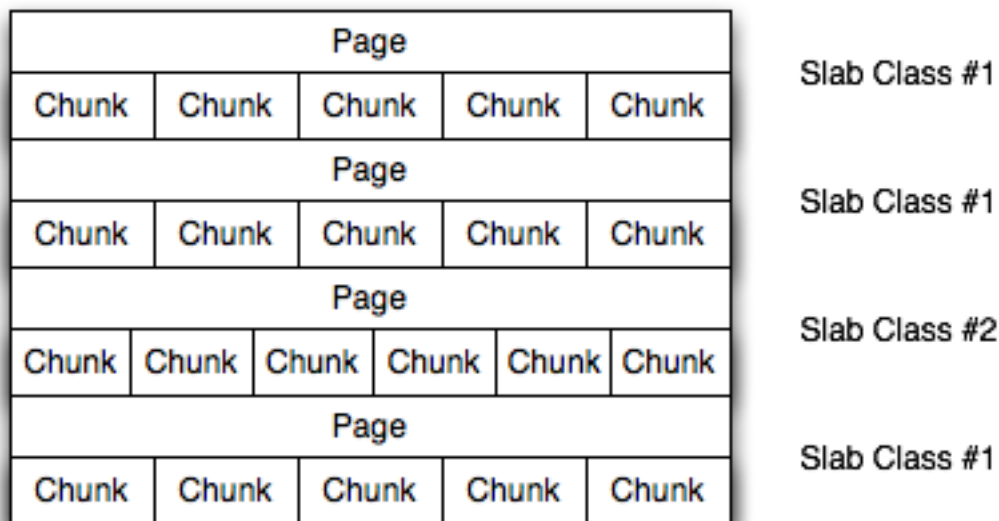

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 14.9, “Memory Allocation in `memcached`”](#).

#### **Figure 14.9. Memory Allocation in `memcached`**

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for  $104 \times 1.25$ , or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 14.6.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

### 14.6.2.7. `memcached` thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distribution to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with

another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

### 14.6.2.8. `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

The lowest verbosity level shows you:

- Errors and warnings
- Transient errors
- Protocol and socket errors, including exhausting available connections
- Each registered client connection, including the socket descriptor number and the protocol used.

For example:

```
32: Client using the ascii protocol
33: Client using the ascii protocol
```

Note that the socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```
<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d
```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
slab class 1: chunk size      80 perslab 13107
slab class 2: chunk size     104 perslab 10082
slab class 3: chunk size     136 perslab  7710
slab class 4: chunk size     176 perslab  5957
slab class 5: chunk size     224 perslab  4681
slab class 6: chunk size     280 perslab  3744
slab class 7: chunk size     352 perslab  2978
slab class 8: chunk size     440 perslab  2383
slab class 9: chunk size     552 perslab  1899
slab class 10: chunk size    696 perslab  1506
```

```

slab class 11: chunk size 872 perslab 1202
slab class 12: chunk size 1096 perslab 956
slab class 13: chunk size 1376 perslab 762
slab class 14: chunk size 1720 perslab 609
slab class 15: chunk size 2152 perslab 487
slab class 16: chunk size 2696 perslab 388
slab class 17: chunk size 3376 perslab 310
slab class 18: chunk size 4224 perslab 248
slab class 19: chunk size 5280 perslab 198
slab class 20: chunk size 6600 perslab 158
slab class 21: chunk size 8256 perslab 127
slab class 22: chunk size 10320 perslab 101
slab class 23: chunk size 12904 perslab 81
slab class 24: chunk size 16136 perslab 64
slab class 25: chunk size 20176 perslab 51
slab class 26: chunk size 25224 perslab 41
slab class 27: chunk size 31536 perslab 33
slab class 28: chunk size 39424 perslab 26
slab class 29: chunk size 49280 perslab 21
slab class 30: chunk size 61600 perslab 17
slab class 31: chunk size 77000 perslab 13
slab class 32: chunk size 96256 perslab 10
slab class 33: chunk size 120320 perslab 8
slab class 34: chunk size 150400 perslab 6
slab class 35: chunk size 188000 perslab 5
slab class 36: chunk size 235000 perslab 4
slab class 37: chunk size 293752 perslab 3
slab class 38: chunk size 367192 perslab 2
slab class 39: chunk size 458992 perslab 2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)

```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```

shell> memcached -f 4 -m lg -vv
slab class 1: chunk size 80 perslab 13107
slab class 2: chunk size 320 perslab 3276
slab class 3: chunk size 1280 perslab 819
slab class 4: chunk size 5120 perslab 204
slab class 5: chunk size 20480 perslab 51
slab class 6: chunk size 81920 perslab 12
slab class 7: chunk size 327680 perslab 3
...

```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```

32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key

```

```

>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key1 1 36
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545

```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the [memcached](#) server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if [memcached](#) is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```

<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.

```

All of the verbosity levels in [memcached](#) are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using [memcached](#). Therefore, use in production or deployment environments is not recommended.

### 14.6.3. [memcached](#) Interfaces

A number of interfaces from different languages exist for interacting with [memcached](#) servers and storing and retrieving information. Interfaces for the most common language platforms including Perl, PHP, Python, Ruby, C and Java.

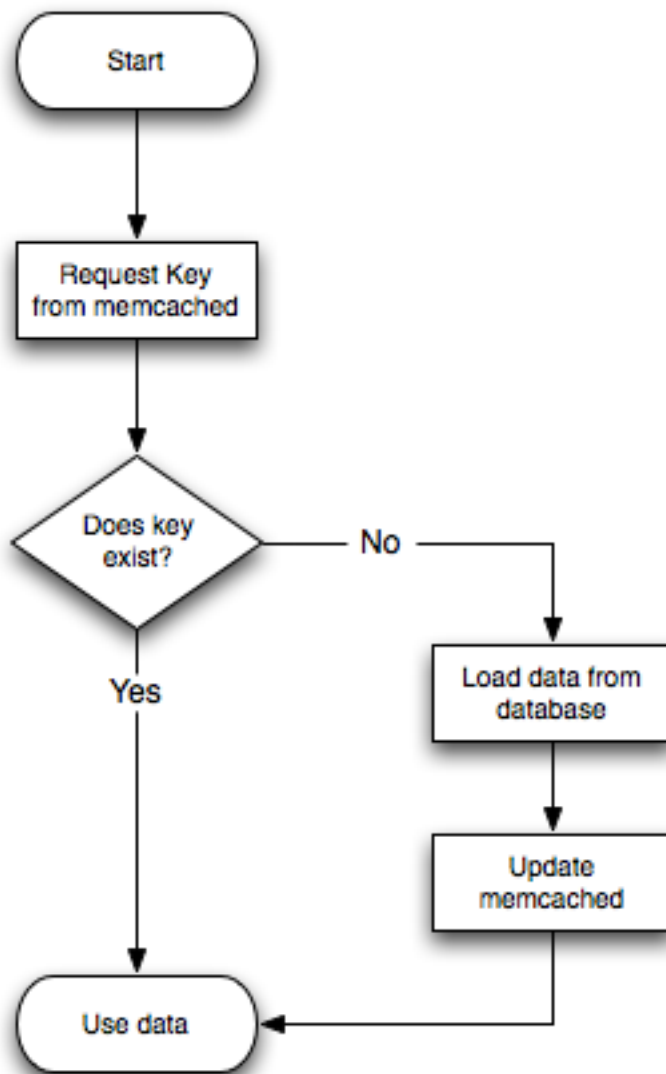

Data stored into a [memcached](#) server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash. It is not possible to structure or otherwise organize the information stored in the cache. To store information in a structured way, you must use 'formatted' keys.

The following tips may be useful to you when using [memcached](#):

The general sequence for using [memcached](#) in any language as a caching solution is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 14.10, "Typical \[memcached\]\(#\) Application Flowchart"](#).

Figure 14.10. Typical `memcached` Application Flowchart

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, even though the language specific mechanics may be different:

- `get(key)`: Retrieves information from the cache. Returns the value if it exists, or `NULL`, `nil`, or `undefined` or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])`: Sets the key in the cache to the specified value. Note that this either updates an existing key if it already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the key expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days ( $30 \times 24 \times 60 \times 60$ ), or an absolute time (epoch) if larger than this value.
- `add(key, value [, expiry])`: Adds the key to the cache, if the specified key doesn't already exist.
- `replace(key, value [, expiry])`: Replaces the `value` of the specified `key`, only if the key already exists.

- `delete(key [, time])`: Deletes the `key` from the cache. If you supply a `time`, then adding a value with the specified `key` is blocked for the specified period.
- `incr(key [, value])`: Increments the specified `key` by one or the specified `value`.
- `decr(key [, value])`: Decrements the specified `key` by one or the specified `value`.
- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

For all languages and interfaces, use `memcached` to store full items, rather than simply caching single rows of information from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. You then save the complete object into the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

### 14.6.3.1. Using `libmemcached`

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides a wealth of functions and operational systems not always exposed in the other interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, there are a number of utility functions that provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run configure, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get` or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);
```

```

if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr, "Added server successfully\n");
else
    fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr, "Key stored successfully\n");
else
    fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));

return 0;
}

```

You can test the success of an operation by using the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, you must specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```

shell> memc_basic
Added server successfully
Key stored successfully

```

#### 14.6.3.1.1. libmemcached Base Functions

The base `libmemcached` functions enable you to create, destroy and clone the main `memcached_st` structure that is used to interface to the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Free the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clone an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

#### 14.6.3.1.2. libmemcached Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are given below:

```

memcached_return
    memcached_server_add (memcached_st *ptr,
                          char *hostname,
                          unsigned int port);

```

Add a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```

memcached_return
    memcached_server_add_unix_socket (memcached_st *ptr,
                                      char *socket);

```

Add a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Return a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *  
    memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return  
    memcached_server_push (memcached_st *ptr,  
                           memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *  
    memcached_server_list_append (memcached_server_st *ptr,  
                                   char *hostname,  
                                   unsigned int port,  
                                   memcached_return *error);
```

Add a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Return the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Free up the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

### 14.6.3.1.3. libmemcached Set Functions

The set related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (add, replace, prepend, append). For example, the function definition for `memcached_set()` is:

```
memcached_return  
    memcached_set (memcached_st *ptr,  
                   const char *key,  
                   size_t key_length,  
                   const char *value,  
                   size_t value_length,  
                   time_t expiration,  
                   uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see [Section 14.6.3.1.5, “libmemcached Behaviors”](#).

The following table outlines the remainder of the set-related functions.

<b>libmemcached Function</b>	<b>Equivalent to</b>
<code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>set()</code> operation.
<code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>add()</code> function.
<code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>replace()</code> .
<code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>	Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .
<code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>	Appends the specified <code>value</code> after the current value of the specified <code>key</code> .
<code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>	Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.
<code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>add()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_prepend()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_append()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_cas()</code> , but has the option of an additional master key that can be used to identify an individual server.

The `by_key` methods add two further arguments, the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
                    const char *master_key,
                    size_t master_key_length,
                    const char *key,
                    size_t key_length,
                    const char *value,
                    size_t value_length,
                    time_t expiration,
                    uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

#### 14.6.3.1.4. libmemcached Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. The function returns a string pointer to the returned value for a corresponding key.

```
char *memcached_get (memcached_st *ptr,
                    const char *key, size_t key_length,
                    size_t *value_length,
                    uint32_t *flags,
                    memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
                char **keys, size_t *key_length,
                unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                      const char *key, size_t *key_length,
                      size_t *value_length,
                      uint32_t *flags,
                      memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;

    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;

    memc = memcached_create(NULL);

    servers = memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc = memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    for(x = 0; x < 3; x++)
    {
        key_length[x] = strlen(keys[x]);
        value_length[x] = strlen(values[x]);

        rc = memcached_set(memc, keys[x], key_length[x], values[x],
                          value_length[x], (time_t)0, (uint32_t)0);
        if (rc == MEMCACHED_SUCCESS)
            fprintf(stderr, "Key %s stored successfully\n", keys[x]);
        else
            fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));
    }

    rc = memcached_mget(memc, keys, key_length, 3);

    if (rc == MEMCACHED_SUCCESS)
    {
        while ((return_value = memcached_fetch(memc, return_key, &return_key_length,
                                              &return_value_length, &flags, &rc)) != NULL)
        {
            if (rc == MEMCACHED_SUCCESS)
            {
                fprintf(stderr, "Key %s returned %s\n", return_key, return_value);
            }
        }
    }
}
```

```

    return 0;
}

```

Running the above application:

```

shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green

```

#### 14.6.3.1.5. libmemcached Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```

memcached_return
memcached_behavior_set (memcached_st *ptr,
                        memcached_behavior flag,
                        uint64_t data);

```

To get the current behavior setting:

```

uint64_t
memcached_behavior_get (memcached_st *ptr,
                        memcached_behavior flag);

```

Behavior	Description
<code>MEMCACHED_BEHAVIOR_NO_BLOCK</code>	Caused <code>libmemcached</code> to use asynchronous I/O.
<code>MEMCACHED_BEHAVIOR_TCP_NODELAY</code>	Turns on no-delay for network sockets.
<code>MEMCACHED_BEHAVIOR_HASH</code>	Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include <code>MEMCACHED_HASH_DEFAULT</code> , <code>MEMCACHED_HASH_MD5</code> , <code>MEMCACHED_HASH_CRC</code> , <code>MEMCACHED_HASH_FNV1_64</code> , <code>MEMCACHED_HASH_FNV1A_64</code> , <code>MEMCACHED_HASH_FNV1_32</code> , and <code>MEMCACHED_HASH_FNV1A_32</code> .
<code>MEMCACHED_BEHAVIOR_DISTRIBUTION</code>	Changes the method of selecting the server used to store a given value. The default method is <code>MEMCACHED_DISTRIBUTION_MODULA</code> . You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> . <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> .
<code>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</code>	Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.
<code>MEMCACHED_BEHAVIOR_SUPPORT_CAS</code>	Support CAS operations. By default, this is disabled because it imposes a performance penalty.
<code>MEMCACHED_BEHAVIOR_KETAMA</code>	Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code> .
<code>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</code>	Modify the timeout value used by <code>poll()</code> . Supply a <code>signed int</code> pointer for the timeout value.
<code>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</code>	Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.
<code>MEMCACHED_BEHAVIOR_VERIFY_KEY</code>	Forces <code>libmemcached</code> to verify that a specified key is valid.
<code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code>	If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.

Behavior	Description
<code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code>	In nonblocking mode this changes the value of the timeout during socket connection.

#### 14.6.3.1.6. `libmemcached` Command-line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command line utilities that can be useful when working with and debugging `memcached` applications.

All of the command line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file names as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

#### 14.6.3.2. Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. You should install the module using your hosts native package management system. Alternatively, you can install the module using [CPAN](#):

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
}
```

};

**Note**

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host by host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a UNIX socket (for example `/tmp/sock/memcached`). You can also specify the server with a weight (indicating how much more frequently the server should be used during hashing) by specifying an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

Cache::Memcached Function	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>get_multi(keys)</code>	Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code>
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server
my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
```

```

$filmkey =~ s/ /_/;
# Load the data from the cache
my $filmdata = $cache->get($filmkey);
# If the data wasn't in the cache, then we load it from the database
if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);
    if (defined($filmdata))
    {
# Set the data into the cache, using the key
        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filmname\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmname) = @_;
    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";
    $dbh = DBI->connect($dsn, 'sakila','password');
    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                    $dbh->quote($filmname)));

    if (!defined($filmbase))
    {
        return (undef);
    }

    $filmbase->{stars} =
        $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                         'from film_actor left join (actor) ' .
                                         'on (film_actor.actor_id = actor.actor_id) ' .
                                         'where film_id=%s',
                                         $dbh->quote($filmbase->{film_id})));

    return($filmbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to memcache. When calling it for a film that does not exist, you get this result:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached

```

When accessing a film that has already been added to the cache:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached

```

### 14.6.3.3. Using MySQL and [memcached](#) with Python

The Python [memcache](#) module interfaces to [memcached](#) servers, and is written in pure python (that is, without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```
python setup.py install
```

```

running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43

```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. Serialization of Python structures is handled by using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class:

```

import memcache
memc = memcache.Client(['127.0.0.1:11211'])

```

The first argument should be an array of strings containing the server and port number for each `memcached` instance to use. You can enable debugging by setting the optional `debug` parameter to 1.

By default, the hashing mechanism used is `crc32`. This provides a basic module hashing algorithm for selecting among multiple servers. You can change the function used by setting the value of `memcache.serverHashFunction` to the alternate function to use. For example:

```

from zlib import Adler32
memcache.serverHashFunction = Adler32

```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. A summary of the supported functions is provided in the following table.

Python <code>memcache</code> Function	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>get_multi(keys)</code>	Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code>
<code>set_multi(dict [, expiry [, key_prefix]])</code>	Sets multiple key/value pairs from the supplied <code>dict</code> .
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>prepend(key, value [, expiry])</code>	Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>append(key, value [, expiry])</code>	Appends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>delete()</code>	Generic <code>delete()</code>
<code>delete_multi(keys [, expiry [, key_prefix]])</code>	Deletes all the keys from the hash matching each string in the array <code>keys</code> .
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

### Note

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```

memc.get_multi(['a', 'b'], key_prefix='users:')

```

The function retrieves the keys `users:a` and `users:b` from the servers.

An example showing the storage and retrieval of information to a [memcache](#) instance, loading the raw data from MySQL, is shown below:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the [memcached](#) server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

The data is automatically serialized using [cPickle/pickle](#). This means when you load the data back from [memcached](#), you can use the object directly. In the example above, the information stored to [memcached](#) is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from [memcached](#) and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically, but be aware that serialization of Python data may be incompatible with other interfaces and languages. You can change the serialization module used during initialization, for example to use JSON, which is more easily exchanged.

#### 14.6.3.4. Using MySQL and [memcached](#) with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP [memcache](#) extensions, you must build PHP using the `--enable-memcache` option to [configure](#) when building from source.

If you are installing on a Red Hat based server, you can install the [php-pecl-memcache](#) RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian based distributions, use the [php-memcache](#) package.

You can set global runtime configuration options by specifying the values in the following table within your [php.ini](#) file.

Configuration option	Default	Description
<a href="#">memcache.allow_failover</a>	1	Specifies whether another server in the list should be queried if the first server selected fails.
<a href="#">memcache.max_failover_attempts</a>	20	Specifies the number of servers to try before returning a failure.
<a href="#">memcache.chunk_size</a>	8192	Defines the size of network chunks used to exchange data

Configuration option	Default	Description
		with the <a href="#">memcached</a> server.
<code>memcache.default_port</code>	11211	Defines the default port to use when communicating with the <a href="#">memcached</a> servers.
<code>memcache.hash_strategy</code>	standard	Specifies which hash strategy to use. Set to <a href="#">consistent</a> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <a href="#">standard</a> , an older (modula) strategy is used that potentially uses different servers for storage.
<code>memcache.hash_function</code>	crc32	Specifies which function to use when mapping keys to servers. <a href="#">crc32</a> uses the standard CRC32 hash. <a href="#">fnv</a> uses the FNV-1a hashing algorithm.

To create a connection to a [memcached](#) server, create a new [Memcache](#) object and then specify the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple [memcached](#) servers, you need to add servers to the memcache object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                        [, int $weight [, int $timeout [, int $retry_interval
                        [, bool $status [, callback $failure_callback
                        ]]]]] ] )
```

The server management mechanism within the [php-memcache](#) module is a critical part of the interface as it controls the main interface to the [memcached](#) instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two [memcached](#) instances:

```
<?php
$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. You can enable persistent connections to [memcached](#) instances by setting the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by [memcached](#), as shown in this table.

PECL <a href="#">memcache</a> Function	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>set()</code>	Generic <code>set()</code>
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>increment()</code>	Generic <code>incr()</code>

PECL <code>memcache</code> Function	Equivalent to
<code>decrement()</code>	Generic <code>decr()</code>

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php
$memc = new Memcache;
$memc->addServer('localhost','11211');
?>

<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Simple Memcache Lookup</title>
</head>
<body>
<form method="post">
  <p><b>Film</b>: <input type="text" size="20" name="film"></p>
<input type="submit">
</form>
<hr/>
<?php
    echo "Loading data...\n";
$value = $memc->get($_REQUEST['film']);
if ($value)
{
    printf("<p>Film data for %s loaded from memcache</p>", $value['title']);
    foreach (array_keys($value) as $key)
    {
        printf("<p><b>%s</b>: %s</p>", $key, $value[$key]);
    }
}
else
{
    $con = new mysqli('localhost','sakila','password','sakila') or
        die("<h1>Database problem</h1>" . mysqli_connect_error());

    $result = $con->query(sprintf('select * from film where title = "%s"', $_REQUEST['film']));

    $row = $result->fetch_array(MYSQLI_ASSOC);

    $memc->set($row['title'], $row);

    printf("<p>Loaded %s from MySQL</p>", $row['title']);
}
?>
```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding a removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 14.6.3.5. Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
```

```
Install required dependency io-reactor? [Yn] y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += [ "192.168.0.101:11211" ]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table.

Ruby <code>MemCache</code> Method	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>get_hash(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values.
<code>set()</code>	Generic <code>set()</code>
<code>set_many(pairs)</code>	Set the values of the keys and values in the hash <code>pairs</code> .
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

### 14.6.3.6. Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <http://whalin.com/memcached/>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SocketIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally you can configure the `memcached` interface once within a single class and then use this interface throughout the rest of your

application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {
    protected static MemCachedClient mcc = new MemCachedClient();
    static {
        String[] servers =
            {
                "localhost:11211",
            };
        Integer[] weights = { 1 };
        SockIOPool pool = SockIOPool.getInstance();
        pool.setServers( servers );
        pool.setWeights( weights );
    }
}
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key you can use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modular hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `lib-memcached`.

Java <code>com.danga.MemCached</code> Method	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>getMulti(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values.
<code>set()</code>	Generic <code>set()</code>
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

### 14.6.3.7. Using the MySQL `memcached` UDFs

The `memcached` MySQL User Defined Functions (UDFs) enable you to set and retrieve objects from within MySQL 5.0 or greater.

To install the MySQL `memcached` UDFs, download the UDF package from <http://libmemcached.org/>. Unpack the package and run `configure` to configure the build process. When running `configure`, use the `--with-mysql` option and specify the location of

the `mysql_config` command.

```
shell> tar xzf memcached_functions_mysql-0.5.tar.gz
shell> cd memcached_functions_mysql-0.5
shell> ./configure --with-mysql-config=/usr/local/mysql/bin/mysql_config
```

Now build and install the functions:

```
shell> make
shell> make install
```

Copy the MySQL `memcached` UDFs into your MySQL plugins directory:

```
shell> cp /usr/local/lib/libmemcached_functions_mysql* /usr/local/mysql/lib/mysql/plugins/
```

The plugin directory is given by the value of the `plugin_dir` system variable. For more information, see [Section 22.3.2.5, “Compiling and Installing User-Defined Functions”](#).

Once installed, you must initialize the function within MySQL using `CREATE` and specifying the return value and library. For example, to add the `memc_get()` function:

```
mysql> CREATE FUNCTION memc_get RETURNS STRING SONAME "libmemcached_functions_mysql.so";
```

Repeat this process for each function to provide access to within MySQL. Once you have created the association, the information is retained, even over restarts of the MySQL server. You can simplify the process by using the SQL script provided in the `memcached` UDFs package:

```
shell> mysql <sql/install_functions.sql
```

Alternatively, if you have Perl installed, then you can use the supplied Perl script, which checks for the existence of each function and creates the function/library association if it is not already defined:

```
shell> utils/install.pl --silent
```

The `--silent` option installs everything automatically. Without this option, the script asks whether to install each of the available functions.

The interface remains consistent with the other APIs and interfaces. To set up a list of servers, use the `memc_servers_set()` function, which accepts a single string containing and comma-separated list of servers:

```
mysql> SELECT memc_servers_set('192.168.0.1:11211,192.168.0.2:11211');
```

### Note

The list of servers used by the `memcached` UDFs is not persistent over restarts of the MySQL server. If the MySQL server fails, then you must re-set the list of `memcached` servers.

To set a value, use `memc_set`:

```
mysql> SELECT memc_set('myid', 'myvalue');
```

To retrieve a stored value:

```
mysql> SELECT memc_get('myid');
```

The list of functions supported by the UDFs, in relation to the standard protocol functions, is shown in the following table.

MySQL <code>memcached</code> UDF Function	Equivalent to
<code>memc_get()</code>	Generic <code>get()</code>
<code>memc_get_by_key(master_key, key, value)</code>	Like the generic <code>get()</code> , but uses the supplied master key to select the server to use.
<code>memc_set()</code>	Generic <code>set()</code>

MySQL <code>memcached</code> UDF Function	Equivalent to
<code>memc_set_by_key(master_key, key, value)</code>	Like the generic <code>set()</code> , but uses the supplied master key to select the server to use.
<code>memc_add()</code>	Generic <code>add()</code>
<code>memc_add_by_key(master_key, key, value)</code>	Like the generic <code>add()</code> , but uses the supplied master key to select the server to use.
<code>memc_replace()</code>	Generic <code>replace()</code>
<code>memc_replace_by_key(master_key, key, value)</code>	Like the generic <code>replace()</code> , but uses the supplied master key to select the server to use.
<code>memc_prepend(key, value)</code>	Prepend the specified <code>value</code> to the current value of the specified <code>key</code> .
<code>memc_prepend_by_key(master_key, key, value)</code>	Prepend the specified <code>value</code> to the current value of the specified <code>key</code> , but uses the supplied master key to select the server to use.
<code>memc_append(key, value)</code>	Append the specified <code>value</code> to the current value of the specified <code>key</code> .
<code>memc_append_by_key(master_key, key, value)</code>	Append the specified <code>value</code> to the current value of the specified <code>key</code> , but uses the supplied master key to select the server to use.
<code>memc_delete()</code>	Generic <code>delete()</code>
<code>memc_delete_by_key(master_key, key, value)</code>	Like the generic <code>delete()</code> , but uses the supplied master key to select the server to use.
<code>memc_increment()</code>	Generic <code>incr()</code>
<code>memc_decrement()</code>	Generic <code>decr()</code>

The respective `*_by_key()` functions are useful to store a specific value into a specific `memcached` server, possibly based on a differently calculated or constructed key.

The `memcached` UDFs include some additional functions:

- `memc_server_count()`

Returns a count of the number of servers in the list of registered servers.

- `memc_servers_set_behavior(behavior_type, value), memc_set_behavior(behavior_type, value)`

Set behaviors for the list of servers. These behaviors are identical to those provided by the `libmemcached` library. For more information on `libmemcached` behaviors, see [Section 14.6.3.1, “Using libmemcached”](#).

You can use the behavior name as the `behavior_type`:

```
mysql> SELECT memc_servers_behavior_set("MEMCACHED_BEHAVIOR_KETAMA",1);
```

- `memc_servers_behavior_get(behavior_type), memc_get_behavior(behavior_type, value)`

Returns the value for a given behavior.

- `memc_list_behaviors()`

Returns a list of the known behaviors.

- `memc_list_hash_types()`

Returns a list of the supported key-hashing algorithms.

- `memc_list_distribution_types()`

Returns a list of the supported distribution types to be used when selecting a server to use when storing a particular key.

- `memc_libmemcached_version()`

Returns the version of the `libmemcached` library.

- `memc_stats()`

Returns the general statistics information from the server.

### 14.6.3.8. memcached Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol you can use a simple text based interface for the exchange of information.

#### 14.6.3.8.1. Using the TCP text protocol

When communicating with `memcached` you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (`cas`):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- **command:** The command name.
  - `set`: Store value against key
  - `add`: Store this value against key if the key does not already exist
  - `replace`: Store this value against key if the key already exists
  - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.

- **key**: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- **flags**: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- **exptime**: The expiry time, or zero for no expiry.
- **length**: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
- **casunique**: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- **noreply**: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see [Table 14.2, “memcached Protocol Responses”](#).

- **Retrieval commands**: `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 .... keyn]  
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- **key**: The key name.
- **flags**: The value of the flag integer supplied to the `memcached` server when the value was stored.
- **bytes**: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- **casunique**: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n  
VALUE xyzkey 0 6\r\n  
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands**: `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- **key**: The key name.

- **time**: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse **add** or **replace** commands on this key. All **add**, **replace**, **get**, and **gets** commands fail during this period. **set** operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- **noreply**: Tells the server not to reply to the command.

Responses to the command are either **DELETED** to indicate that the key was successfully removed, or **NOT\_FOUND** to indicate that the specified key could not be found.

- **Increment/Decrement**: **incr**, **decr**

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- **key**: The key name.
- **value**: An integer to be used as the increment or decrement value.
- **noreply**: Tells the server not to reply to the command.

The response is:

- **NOT\_FOUND**: The specified key could not be located.
- **value**: The new value of the specified key.

Values are assumed to be unsigned. For **decr** operations the value is never decremented below 0. For **incr** operations, the value wraps around the 64-bit maximum.

- **Statistics commands**: **stats**

The **stats** command provides detailed statistical information about the current status of the **memcached** instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- **name**: The optional name of the statistics to return. If not specified, the general statistics are returned.
- **value**: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, **END**.

For more information, see [Section 14.6.4, “Getting memcached Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

**Table 14.1. memcached Command Reference**

Command	Command Formats
set	set key flags exptime length, set key flags exptime length noreply
add	add key flags exptime length, add key flags exptime length noreply
replace	replace key flags exptime length, replace key flags exptime length noreply
append	append key length, append key length noreply
prepend	prepend key length, prepend key length noreply
cas	cas key flags exptime length casunique, cas key flags exptime length casunique noreply
get	get key1 [key2 ... keyn]
gets	
delete	delete key, delete key noreply, delete key expiry, delete key expiry noreply
incr	incr key, incr key noreply, incr key value, incr key value noreply
decr	decr key, decr key noreply, decr key value, decr key value noreply
stat	stat, stat name, stat name value

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 14.2. memcached Protocol Responses**

String	Description
STORED	Value has successfully been stored.
NOT_STORED	The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code> ), or where the item has already been set to be deleted.
EXISTS	When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.
NOT_FOUND	The item you are trying to store, update or delete does not exist or has already been deleted.
ERROR	You submitted a nonexistent command name.
CLIENT_ERROR error-string	There was an error in the input line, the detail is contained in <code>errorstring</code> .
SERVER_ERROR error-string	There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.
VALUE key flags length	The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block are returned, of the specified <code>length</code> .
DELETED	The requested key was deleted from the server.
STAT name value	A line of statistics data.
END	The end of the statistics data.

#### 14.6.4. Getting memcached Statistics

The `memcached` system has a built in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can prove be very useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the [Section 14.6.4.2, “memcached Slabs Statistics”](#) and [Section 14.6.4.1, “memcached General Statistics”](#) information. For more information, see [Section 14.6.4.6, “Using memcached-tool”](#).

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
  'hosts' => {
    'localhost:11211' => {
      'misc' => {
        'bytes' => '2421',
        'curr_connections' => '3',
        'connection_structures' => '56',
        'pointer_size' => '32',
        'time' => '1211440166',
        'total_items' => '410956',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'evictions' => '0',
        'curr_items' => '31',
        'pid' => '23599',
        'limit_maxbytes' => '67108864',
        'uptime' => '1254',
        'rusage_user' => '9.857805',
        'cmd_get' => '838451',
        'rusage_system' => '34.096988',
        'version' => '1.2.5',
        'get_hits' => '581511',
        'bytes_read' => '46665716',
```

```

        'threads' => '1',
        'total_connections' => '3104',
        'get_misses' => '256940'
    },
    'sizes' => {
        '128' => '16',
        '64' => '15'
    }
}

'self' => {},
'total' => {
    'cmd_get' => 838451,
    'bytes' => 2421,
    'get_hits' => 581511,
    'connection_structures' => 56,
    'bytes_read' => 46665716,
    'total_items' => 410956,
    'total_connections' => 3104,
    'cmd_set' => 588167,
    'bytes_written' => 35715151,
    'curr_items' => 31,
    'get_misses' => 256940
}
};

```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 14.6.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 14.6.4.2, “memcached Slabs Statistics”](#).
- Item statistics (`items`), see [Section 14.6.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 14.6.4.4, “memcached Size Statistics”](#).
- Detailed status (`detail`), see [Section 14.6.4.5, “memcached Detail Statistics”](#).

#### 14.6.4.1. memcached General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- **32u**: 32-bit unsigned integer
- **64u**: 64-bit unsigned integer
- **32u32u**: Two 32-bit unsigned integers separated by a colon
- **String**: Character string

Statistic	Data type	Description	Version
pid	32u	Process ID of the <code>memcached</code> instance.	
uptime	32u	Uptime (in seconds) for this <code>memcached</code> instance.	
time	32u	Current time (as epoch).	
version	string	Version string of this instance.	
pointer_size	string	Size of pointers for this host specified in bits (32 or 64).	
rusage_user	32u:32u	Total user time for this instance (seconds:microseconds).	
rusage_system	32u:32u	Total system time for this instance (seconds:microseconds).	
curr_items	32u	Current number of items stored by this instance.	
total_items	32u	Total number of items stored during the life of this instance.	

Statistic	Data type	Description	Version
bytes	64u	Current number of bytes used by this server to store items.	
curr_connections	32u	Current number of open connections.	
total_connections	32u	Total number of connections opened since the server started running.	
connection_structures	32u	Number of connection structures allocated by the server.	
cmd_get	64u	Total number of retrieval requests ( <a href="#">get</a> operations).	
cmd_set	64u	Total number of storage requests ( <a href="#">set</a> operations).	
get_hits	64u	Number of keys that have been requested and found present.	
get_misses	64u	Number of items that have been requested and not found.	
delete_hits	64u	Number of keys that have been deleted and found present.	1.3.x
delete_misses	64u	Number of items that have been delete and not found.	1.3.x
incr_hits	64u	Number of keys that have been incremented and found present.	1.3.x
incr_misses	64u	Number of items that have been incremented and not found.	1.3.x
decr_hits	64u	Number of keys that have been decremented and found present.	1.3.x
decr_misses	64u	Number of items that have been decremented and not found.	1.3.x
cas_hits	64u	Number of keys that have been compared and swapped and found present.	1.3.x
cas_misses	64u	Number of items that have been compared and swapped and not found.	1.3.x
cas_badvalue	64u	Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value.	1.3.x
evictions	64u	Number of valid items removed from cache to free memory for new items.	
bytes_read	64u	Total number of bytes read by this server from network.	
bytes_written	64u	Total number of bytes sent by this server to network.	
limit_maxbytes	32u	Number of bytes this server is permitted to use for storage.	
threads	32u	Number of worker threads requested.	
conn_yields	64u	Number of yields for connections (related to the <a href="#">-R</a> option).	1.4.0

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of [get\\_misses](#) may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache [get\\_hits](#). If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the [memcached](#) instances to improve the hit ratio.

A large number of [evictions](#) from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

#### 14.6.4.2. [memcached](#) Slabs Statistics

To get the [slabs](#) statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
```

```

STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END

```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The different parameters returned for each chunk size and the totals are shown in the following table.

Statistic	Description	Version
chunk_size	Space allocated to each chunk within this slab class.	
chunks_per_page	Number of chunks within a single page for this slab class.	
total_pages	Number of pages allocated to this slab class.	
total_chunks	Number of chunks allocated to the slab class.	
used_chunks	Number of chunks allocated to an item..	
free_chunks	Number of chunks not yet allocated to items.	
free_chunks_end	Number of free chunks at the end of the last allocated page.	
get_hits	Number of get hits to this chunk	1.3.x
cmd_set	Number of set commands on this chunk	1.3.x
delete_hits	Number of delete hits to this chunk	1.3.x
incr_hits	Number of increment hits to this chunk	1.3.x
decr_hits	Number of decrement hits to this chunk	1.3.x
cas_hits	Number of CAS hits to this chunk	1.3.x
cas_badval	Number of CAS hits on this chunk where the existing value did not match	1.3.x
mem_requested	The true amount of memory of memory requested within this chunk	1.4.1

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

Statistic	Description	Version
active_slabs	Total number of slab classes allocated.	
total_malloced	Total amount of memory allocated to slab pages.	

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

### 14.6.4.3. memcached Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

Statistic	Description	
<code>number</code>	The number of items currently stored in this slab class.	
<code>age</code>	The age of the oldest item within the slab class, in seconds.	
<code>evicted</code>	The number of items evicted to make way for new entries.	
<code>evicted_time</code>	The time of the last evicted entry	
<code>evicted_nonzero</code>	The time of the last evicted non-zero entry	1.4.0
<code>outofmemory</code>	The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect).	
<code>tailrepairs</code>	Number of times the entries for a particular ID need repairing	

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

### 14.6.4.4. memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

#### Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this

may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

#### 14.6.4.5. `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and del operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

#### 14.6.4.6. Using `memcached-tool`

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
# Item_Size Max_age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0
2 104B 93s 1 16 no 0 0 0
3 136B 1335s 1 28 no 0 0 0
4 176B 1335s 1 24 no 0 0 0
5 224B 1335s 1 32 no 0 0 0
6 280B 1335s 1 34 no 0 0 0
7 352B 1335s 1 36 no 0 0 0
8 440B 1335s 1 46 no 0 0 0
9 552B 1335s 1 58 no 0 0 0
10 696B 1335s 1 66 no 0 0 0
11 872B 1335s 1 89 no 0 0 0
12 1.1K 1335s 1 112 no 0 0 0
13 1.3K 1335s 1 145 no 0 0 0
```

14	1.7K	1335s	1	123	no	0	0	0
15	2.1K	1335s	1	198	no	0	0	0
16	2.6K	1335s	1	199	no	0	0	0
17	3.3K	1335s	1	229	no	0	0	0
18	4.1K	1335s	1	248	yes	36	2	0
19	5.2K	1335s	2	328	no	0	0	0
20	6.4K	1335s	2	316	yes	387	1	0
21	8.1K	1335s	3	381	yes	492	1	0
22	10.1K	1335s	3	303	yes	598	2	0
23	12.6K	1335s	5	405	yes	605	1	0
24	15.8K	1335s	6	384	yes	766	2	0
25	19.7K	1335s	7	357	yes	908	170	0
26	24.6K	1336s	7	287	yes	1012	1	0
27	30.8K	1336s	7	231	yes	1193	169	0
28	38.5K	1336s	4	104	yes	1323	169	0
29	48.1K	1336s	1	21	yes	1287	1	0
30	60.2K	1336s	1	17	yes	1093	169	0
31	75.2K	1337s	1	13	yes	713	168	0
32	94.0K	1337s	1	10	yes	278	168	0
33	117.5K	1336s	1	3	no	0	0	0

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
# Item_Size Max_age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0
2 104B 93s 1 16 no 0 0 0
...
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab
- `Count`: The number of items in this slab
- `Full?`: Whether the slab is fully populated
- `Evicted`: The number of objects evicted from this slab
- `Evict_Time`: The time (in seconds) since the last eviction
- `OOM`: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211 Field Value
accepting_conns 1
bytes 162
bytes_read 485
bytes_written 6820
cas_badval 0
cas_hits 0
cas_misses 0
cmd_flush 0
cmd_get 4
cmd_set 2
conn_yields 0
connection_structures 11
curr_connections 10
curr_items 2
decr_hits 0
decr_misses 1
delete_hits 0
delete_misses 0
evictions 0
get_hits 4
get_misses 0
incr_hits 0
incr_misses 2
```

```
limit_maxbytes      67108864
listen_disabled_num 0
pid                 12981
pointer_size        32
rusage_system       0.013911
rusage_user         0.011876
threads             4
time                1255518565
total_connections    20
total_items          2
uptime              880
version             1.4.2
```

The `memcached-tool` provides

## 14.6.5. memcached FAQ

### Questions

- [15.6.5.1](#): Can MySQL actually trigger/store the changed data to memcached?
- [15.6.5.2](#): Can memcached be run on a Windows environment?
- [15.6.5.3](#): Does the `-L` flag automatically sense how much memory is being used by other memcached?
- [15.6.5.4](#): What is the max size of an object you can store in memcache and is that configurable?
- [15.6.5.5](#): Is it true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?
- [15.6.5.6](#): `memcached` is fast - is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?
- [15.6.5.7](#): How does an event such as a crash of one of the `memcached` servers handled by the `memcached` client?
- [15.6.5.8](#): What's a recommended hardware config for a memcached server? Linux or Windows?
- [15.6.5.9](#): Doing a direct telnet to the memcached port, is that just for that one machine, or does it magically apply across all nodes?
- [15.6.5.10](#): Is memcached more effective for video and audio as opposed to textual read/writes
- [15.6.5.11](#): If you log a complex class (with methods that do calculation etc) will the get from Memcache re-create the class on the way out?
- [15.6.5.12](#): If I have an object larger than a MB, do I have to manually split it or can I configure `memcached` to handle larger objects?
- [15.6.5.13](#): Can `memcached` work with ASPX?
- [15.6.5.14](#): Are there any, or are there any plans to introduce, a framework to hide the interaction of memcached from the application; that is, within hibernate?
- [15.6.5.15](#): So the responsibility lies with the application to populate and get records from the database as opposed to being a transparent cache layer for the db?
- [15.6.5.16](#): How does `memcached` compare to nCache?
- [15.6.5.17](#): We are caching XML by serialising using `saveXML()`, because PHP cannot serialize DOM objects; Some of the XML is variable and is modified per-request. Do you recommend caching then using XPath, or is it better to rebuild the DOM from separate node-groups?
- [15.6.5.18](#): How easy is it to introduce `memcached` to an existing enterprise application instead of inclusion at project design?
- [15.6.5.19](#): Do the memcache UDFs work under 5.1?
- [15.6.5.20](#): Is the data inside of `memcached` secure?

- [15.6.5.21](#): Is `memcached` typically a better solution for improving speed than MySQL Cluster and/or MySQL Proxy?
- [15.6.5.22](#): File socket support for `memcached` from the localhost use to the local memcached server?
- [15.6.5.23](#): How expensive is it to establish a memcache connection? Should those connections be pooled?
- [15.6.5.24](#): What are the advantages of using UDFs when the get/sets are manageable from within the client code rather than the db?
- [15.6.5.25](#): How will the data will be handled when the `memcached` server is down?
- [15.6.5.26](#): How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?
- [15.6.5.27](#): Is compression available?
- [15.6.5.28](#): What speed trade offs is there between `memcached` vs MySQL Query Cache? Where you check `memcached`, and get data from MySQL and put it in `memcached` or just make a query and results are put into MySQL Query Cache.
- [15.6.5.29](#): Can we implement different types of `memcached` as different nodes in the same server - so can there be deterministic and non deterministic in the same server?
- [15.6.5.30](#): What are best practices for testing an implementation, to ensure that it is an improvement over the MySQL query cache, and to measure the impact of `memcached` configuration changes? And would you recommend keeping the configuration very simple to start?

## Questions and Answers

### 15.6.5.1: Can MySQL actually trigger/store the changed data to memcached?

Yes. You can use the MySQL UDFs for `memcached` and either write statements that directly set the values in the `memcached` server, or use triggers or stored procedures to do it for you. For more information, see [Section 14.6.3.7, “Using the MySQL memcached UDFs”](#)

### 15.6.5.2: Can memcached be run on a Windows environment?

No. Currently `memcached` is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

### 15.6.5.3: Does the `-L` flag automatically sense how much memory is being used by other memcached?

No. There is no communication or sharing of information between `memcached` instances.

### 15.6.5.4: What is the max size of an object you can store in memcache and is that configurable?

The default maximum object size is 1MB. In `memcached` 1.4.2 and later you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile `memcached`. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In `memcached` 1.4.2 and higher you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

### 15.6.5.5: Is it true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

### 15.6.5.6: `memcached` is fast - is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with `memcached` then there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem then eventually your request will timeout and return no result so your application will need to load from MySQL again.

**15.6.5.7: How does an event such as a crash of one of the `memcached` servers handled by the `memcached` client?**

There is no automatic handling of this. If your client fails to get a response from a server then it should fall back to loading the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 14.6.2.4, “memcached Hashing/Distribution Types”](#).

**15.6.5.8: What's a recommended hardware config for a `memcached` server? Linux or Windows?**

`memcached` is only available on Unix/Linux, so using a Windows machine is not an option. Outside of this, `memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. The point is not that you should necessarily deploy a dedicated `memcached` server. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

If you want to build and deploy a dedicated `memcached` servers, then you use a relatively low-power CPU, lots of RAM and one or more Gigabit Ethernet interfaces.

**15.6.5.9: Doing a direct telnet to the `memcached` port, is that just for that one machine, or does it magically apply across all nodes?**

Just one. There is no communication between different instances of `memcached`, even if each instance is running on the same machine.

**15.6.5.10: Is `memcached` more effective for video and audio as opposed to textual read/writes**

`memcached` doesn't care what information you are storing. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` is 1MB, but can be configured to be larger by using the `-I` option in `memcached` 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using `memcached` with audio and video content you will probably want to increase the maximum object size. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**15.6.5.11: If you log a complex class (with methods that do calculation etc) will the get from Memcache re-create the class on the way out?**

In general, yes. If the serialization method within the API/language that you are using supports it, then methods and other information will be stored and retrieved.

**15.6.5.12: If I have an object larger than a MB, do I have to manually split it or can I configure `memcached` to handle larger objects?**

You would have to manually split it. `memcached` is very simple, you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

**15.6.5.13: Can `memcached` work with ASPX?**

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or Visual-Basic, and if you are using ASP.NET then there is a C# `memcached` library. For more information, see [.](#)

**15.6.5.14: Are there any, or are there any plans to introduce, a framework to hide the interaction of `memcached` from the application; that is, within hibernate?**

There are lots of projects working with `memcached`. There is a Google Code implementation of Hibernate and `memcached` working together. See <http://code.google.com/p/hibernate-memcached/>.

**15.6.5.15: So the responsibility lies with the application to populate and get records from the database as opposed to being a transparent cache layer for the db?**

Yes. You load the data from the database and write it into the cache provided by `memcached`. Using `memcached` as a simple data-

base row cache, however, is probably inefficient. The best way to use [memcached](#) is to load all of the information from the database relating to a particular object, and then cache the entire object. For example, in a blogging environment, you might load the blog, associated comments, categories and so on, and then cache all of the information relating to that blog post. The reading of the data from the database will require multiple SQL statements and probably multiple rows of data to complete, which is time consuming. Loading the entire blog post and the associated information from [memcached](#) is just one operation and doesn't involve using the disk or parsing the SQL statement.

**15.6.5.16: How does [memcached](#) compare to nCache?**

The main benefit of [memcached](#) is that is very easy to deploy and works with a wide range of languages and environments, including .NET, Java, Perl, Python, PHP, even MySQL. [memcached](#) is also very lightweight in terms of systems and requirements, and you can easily add as many or as few [memcached](#) servers as you need without changing the individual configuration. [memcached](#) does require additional modifications to the application to take advantage of functionality such as multiple [memcached](#) servers.

**15.6.5.17: We are caching XML by serialising using `saveXML()`, because PHP cannot serialize DOM objects; Some of the XML is variable and is modified per-request. Do you recommend caching then using XPath, or is it better to rebuild the DOM from separate node-groups?**

You would need to test your application using the different methods to determine this information. You may find that the default serialization within PHP may allow you to store DOM objects directly into the cache.

**15.6.5.18: How easy is it to introduce [memcached](#) to an existing enterprise application instead of inclusion at project design?**

In general, it is very easy. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data and then fall back to the old method, and to update the cache with information once the data has been read.

[memcached](#) is designed to be deployed very easily, and you shouldn't require significant architectural changes to your application to use [memcached](#).

**15.6.5.19: Do the memcache UDFs work under 5.1?**

Yes.

**15.6.5.20: Is the data inside of [memcached](#) secure?**

No, there is no security required to access or update the information within a [memcached](#) instance, which means that anybody with access to the machine has the ability to read, view and potentially update the information. If you want to keep the data secure, you can encrypt and decrypt the information before storing it. If you want to restrict the users capable of connecting to the server, your only choice is to either disable network access, or use IPTables or similar to restrict access to the [memcached](#) ports to a select set of hosts.

**15.6.5.21: Is [memcached](#) typically a better solution for improving speed than MySQL Cluster and/or MySQL Proxy?**

Both MySQL Cluster and MySQL Proxy still require access to the underlying database to retrieve the information. This implies both a parsing overhead for the statement and, often, disk based access to retrieve the data you have selected.

The advantage of [memcached](#) is that you can store entire objects or groups of information that may require multiple SQL statements to obtain. Restoring the result of 20 SQL statements formatted into a structure that your application can use directly without requiring any additional processing is always going to be faster than building that structure by loading the rows from a database.

**15.6.5.22: File socket support for [memcached](#) from the localhost use to the local [memcached](#) server?**

You can use the `-s` option to [memcached](#) to specify the location of a file socket. This automatically disables network support.

**15.6.5.23: How expensive is it to establish a memcache connection? Should those connections be pooled?**

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a [memcached](#) instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

**15.6.5.24: What are the advantages of using UDFs when the get/sets are manageable from within the client code rather than the db?**

Sometimes you want to be able to update the information within [memcached](#) based on a generic database activity, rather than relying on your client code. For example, you may want to update status or counter information in [memcached](#) through the use of a trigger or stored procedure. For some situations and applications the existing use of a stored procedure for some operations means that

updating the value in `memcached` from the database is easier than separately loading and communicating that data to the client just so the client can talk to `memcached`.

In other situations, when you are using a number of different clients and different APIs, you don't want to have to write (and maintain) the code required to update `memcached` in all the environments. Instead, you do this from within the database and the client never gets involved.

**15.6.5.25: How will the data will be handled when the `memcached` server is down?**

The behavior is entirely application dependent. Most applications will fall back to loading the data from the database (just as if they were updating the `memcached`) information. If you are using multiple `memcached` servers, you may also want to remove a server from the list to prevent the missing server affecting performance. This is because the client will still attempt to communicate the `memcached` that corresponds to the key you are trying to load.

**15.6.5.26: How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?**

They aren't. There is no relationship between MySQL and `memcached` unless your application (or, if you are using the MySQL UDFs for `memcached`, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of `memcached` then the information will only be stored on one of the `memcached` instances anyway. The client uses the key value to determine which `memcached` instance to store the information, it doesn't store the same information across all the instances, as that would be a waste of cache memory.

**15.6.5.27: Is compression available?**

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

**15.6.5.28: What speed trade offs is there between `memcached` vs MySQL Query Cache? Where you check `memcached`, and get data from MySQL and put it in `memcached` or just make a query and results are put into MySQL Query Cache.**

In general, the time difference between getting data from the MySQL Query Cache and getting the exact same data from `memcached` is very small.

However, the benefit of `memcached` is that you can store any information, including the formatted and processed results of many queries into a single `memcached` key. Even if all the queries that you executed could be retrieved from the Query Cache without having to go to disk, you would still be running multiple queries (with network and other overhead) compared to just one for the `memcached` equivalent. If your application uses objects, or does any kind of processing on the information, with `memcached` you can store the post-processed version, so the data you load is immediately available to be used. With data loaded from the Query Cache, you would still have to do that processing.

In addition to these considerations, keep in mind that keeping data in the MySQL Query Cache is difficult as you have no control over the queries that are stored. This means that a slightly unusual query can temporarily clear a frequently used (and normally cached) query, reducing the effectiveness of your Query Cache. With `memcached` you can specify which objects are stored, when they are stored, and when they should be deleted giving you much more control over the information stored in the cache.

**15.6.5.29: Can we implement different types of `memcached` as different nodes in the same server - so can there be deterministic and non deterministic in the same server?**

Yes. You can run multiple instances of `memcached` on a single server, and in your client configuration you choose the list of servers you want to use.

**15.6.5.30: What are best practices for testing an implementation, to ensure that it is an improvement over the MySQL query cache, and to measure the impact of `memcached` configuration changes? And would you recommend keeping the configuration very simple to start?**

The best way to test the performance is to start up a `memcached` instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into `memcached`. Since the APIs handle the serialization of the data, it should just be a one line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from `memcached`. If the data cannot be loaded from `memcached`, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, etc.), rather than using `memcached` as a simple cache of individuals rows of MySQL tables. You should see performance benefits almost immediately.

Keeping the configuration very simple at the start, or even over the long term, is very easy with `memcached`. Once you have the basic structure up and running, the only change you may want to make is to add more servers into the list of servers used by your clients. You

don't need to manage the [memcached](#) servers, and there is no complex configuration, just add more servers to the list and let the client API and the [memcached](#) servers make the decisions.

## 14.7. MySQL Proxy

The MySQL Proxy is an application that communicates over the network using the MySQL network protocol and provides communication between one or more MySQL servers and one or more MySQL clients. Because MySQL Proxy uses the MySQL network protocol, it can be used without modification with any MySQL-compatible client that uses the protocol. This includes the [mysql](#) command-line client, any clients that uses the MySQL client libraries, and any connector that supports the MySQL network protocol.

In the most basic configuration, MySQL Proxy simply interposes itself between the server and clients, passing queries from the clients to the MySQL Server and returning the responses from the MySQL Server to the appropriate client. In more advanced configurations, the MySQL Proxy can also monitor and alter the communication between the client and the server. Query interception enables you to add profiling, and interception of the exchanges is scriptable using the Lua scripting language.

By intercepting the queries from the client, the proxy can insert additional queries into the list of queries sent to the server, and remove the additional results when they are returned by the server. Using this functionality you can return the results from the original query to the client while adding informational statements to each query, for example, to monitor their execution time or progress, and separately log the results.

The proxy enables you to perform additional monitoring, filtering, or manipulation of queries without requiring you to make any modifications to the client and without the client even being aware that it is communicating with anything but a genuine MySQL server.

This documentation covers MySQL Proxy 0.8.2.

### Warning

MySQL Proxy is currently an Alpha release and should not be used within production environments.

### Important

MySQL Proxy is compatible with MySQL 5.0 or later. Testing has not been performed with Version 4.1. Please provide feedback on your experiences using the [MySQL Proxy Forum](#).

### 14.7.1. MySQL Proxy Supported Platforms

MySQL Proxy is currently available as a precompiled binary for the following platforms:

- Linux (including Red Hat, Fedora, Debian, SuSE) and derivatives
- Mac OS X
- FreeBSD
- IBM AIX
- Sun Solaris
- Microsoft Windows (including Microsoft Windows XP, Microsoft Windows Vista, Microsoft Windows Server 2003, Microsoft Windows Server 2008)

### Note

You must have the .NET Framework 1.1 or higher installed.

Other Unix/Linux platforms not listed should be compatible by using the source package and building MySQL Proxy locally.

System requirements for the MySQL Proxy application are the same as the main MySQL server. Currently MySQL Proxy is compatible only with MySQL 5.0.1 and later. MySQL Proxy is provided as a standalone, statically linked binary. You need not have MySQL or Lua installed.

### 14.7.2. Installing MySQL Proxy

You have three choices for installing MySQL Proxy:

- Precompiled binaries are available for a number of different platforms. See [Section 14.7.2.1, “Installing MySQL Proxy from a Binary Distribution”](#).
- You can install from the source code to build on an environment not supported by the binary distributions. See [Section 14.7.2.2, “Installing MySQL Proxy from a Source Distribution”](#).
- The latest version of the MySQL Proxy source code is available through a development repository is the best way to stay up to date with the latest fixes and revisions. See [Section 14.7.2.3, “Installing MySQL Proxy from the Bazaar Repository”](#).

### 14.7.2.1. Installing MySQL Proxy from a Binary Distribution

If you download a binary package, you must extract and copy the package contents to your desired installation directory. The package contains files required by MySQL Proxy, including additional Lua scripts and other components required for execution.

To install, unpack the archive into the desired directory, then modify your `PATH` environment variable so that you can use the `mysql-proxy` command directly:

```
shell> cd /usr/local
shell> tar xzf mysql-proxy-0.8.2-platform.tar.gz
shell> PATH=$PATH:/usr/local/mysql-proxy-0.8.2-platform/sbin
```

To update the path globally on a system, you might need administrator privileges to modify the appropriate `/etc/profile`, `/etc/bashrc`, or other system configuration file.

On Windows, you can update the `PATH` environment variable using this procedure:

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Next select the Advanced tab from the `SYSTEM PROPERTIES` menu that appears, and click the ENVIRONMENT VARIABLES button.
3. Under **SYSTEM VARIABLES**, select Path, then click the EDIT button. The `EDIT SYSTEM VARIABLE` dialogue should appear.

The Microsoft Visual C++ runtime libraries are a requirement for running MySQL Proxy as of version 0.8.2. Users that do not have these libraries must download and install the Microsoft Visual C++ 2008 Service Pack 1 Redistributable Package MFC Security Update. Use the following link to obtain the package:

```
http://www.microsoft.com/download/en/details.aspx?displaylang=en&id=26368
```

### 14.7.2.2. Installing MySQL Proxy from a Source Distribution

You can download a source package and compile the MySQL Proxy yourself. To build from source, you must have the following pre-requisite components installed:

- `libevent` 1.x or higher (1.3b or later is preferred).
- `lua` 5.1.x or higher.
- `glib2` 2.6.0 or higher.
- `pkg-config`.
- `libtool` 1.5 or higher.
- MySQL 5.0.x or higher developer files.

#### ■ Note

On some operating systems, you might need to manually build the required components to get the latest version. If you have trouble compiling MySQL Proxy, consider using a binary distributions instead.

After verifying that the prerequisite components are installed, configure and build MySQL Proxy:

```
shell> tar xzf mysql-proxy-0.8.2.tar.gz
shell> cd mysql-proxy-0.8.2
shell> ./configure
shell> make
```

To test the build, use the `check` target to `make`:

```
shell> make check
```

The tests try to connect to `localhost` using the `root` user. To provide a password, set the `MYSQL_PASSWORD` environment variable:

```
shell> MYSQL_PASSWORD=root_pwd make check
```

You can install using the `install` target:

```
shell> make install
```

By default, `mysql-proxy` is installed into `/usr/local/sbin/mysql-proxy`. The Lua example scripts are installed into `/usr/local/share`.

### 14.7.2.3. Installing MySQL Proxy from the Bazaar Repository

The MySQL Proxy source is available through a public Bazaar repository and is the quickest way to get the latest releases and fixes.

A build from the Bazaar repository requires that the following prerequisite components be installed:

- Bazaar 1.10.0 or later.
- `libtool` 1.5 or higher.
- `autoconf` 2.56 or higher.
- `automake` 1.10 or higher.
- `libevent` 1.x or higher (1.3b or later is preferred).
- `lua` 5.1.x or higher.
- `glib2` 2.4.0 or higher.
- `pkg-config`.
- MySQL 5.0.x or higher developer files.

The `mysql-proxy` source is hosted on Launchpad. To check out a local copy of the Bazaar repository, use `bzr`:

```
shell> bzr branch lp:mysql-proxy
```

The preceding command downloads a complete version of the Bazaar repository for `mysql-proxy`. The main source files are located within the `trunk` subdirectory. The configuration scripts must be generated before you can configure and build `mysql-proxy`. The `autogen.sh` script generates the required configuration scripts for you:

```
shell> sh ./autogen.sh
```

The `autogen.sh` script creates the standard `configure` script, which you then use to configure and build with `make`:

```
shell> ./configure
```

```
shell> make
shell> make install
```

To create a standalone source distribution, identical to the source distribution available for download, use this command:

```
shell> make distcheck
```

The preceding command creates the file `mysql-proxy-0.8.2.tar.gz` (with the corresponding current version) within the current directory.

#### 14.7.2.4. Setting Up MySQL Proxy as a Windows Service

The MySQL distribution on Windows includes the `mysql-proxy-svc.exe` command that enables a MySQL Proxy instance to be managed by the Windows service control manager. You can control the service, including automatically starting and stopping it during boot, reboot and shutdown, without separately running the MySQL Proxy application.

To set up a MySQL Proxy service, use the `sc` command to create a new service using the MySQL Proxy service command. Specify the MySQL Proxy options on the `sc` command line, and identify the service with a unique name. For example, to configure a new MySQL Proxy instance that will automatically start when your system boots, redirecting queries to the local MySQL server:

```
C:\> sc create "Proxy" DisplayName= "MySQL Proxy" start= "auto" »
      binPath= "C:\Program Files\MySQL\mysql-proxy-0.8.2\bin\mysql-proxy-svc.exe »
      --proxy-backend-addresses=127.0.0.1:3306"
```

##### Note

The space following the equal sign after each property is required; failure to include it results in an error.

The preceding command creates a new service called `Proxy`. You can start and stop the service using the `net start|stop` command with the service name. The service is not automatically started after it is created. To start the service:

```
C:\> net start proxy
The MySQL Proxy service is starting.
The MySQL Proxy service was started successfully.
```

You can specify additional command-line options to the `sc` command. You can also set up multiple MySQL Proxy services on the same machine (providing they are configured to listen on different ports and/or IP addresses).

You can delete a service that you have created:

```
C:\> sc delete proxy
```

For more information on creating services using `sc`, see [How to create a Windows service by using Sc.exe](#).

#### 14.7.3. MySQL Proxy Command Options

To start MySQL Proxy, you can run it directly from the command line:

```
shell> mysql-proxy
```

For most situations, you specify at least the host name or address and the port number of the backend MySQL server to which the MySQL Proxy should pass queries.

You can specify options to `mysql-proxy` either on the command line, or by using a configuration file and the `--defaults-file` command-line option to specify the file location.

If you use a configuration file, format it as follows:

- Specify the options within a `[mysql-proxy]` configuration group. For example:

```
[mysql-proxy]
admin-address = host:port
```

- Specify all configuration options in the form of a configuration name and the value to set.
- For options that are a simple toggle on the command line (for example, `--proxy-skip-profiling`), use `true` or `false`. For example, the following is invalid:

```
[mysql-proxy]
proxy-skip-profiling
```

But this is valid:

```
[mysql-proxy]
proxy-skip-profiling = true
```

- Give the configuration file Unix permissions of `0660` (readable and writable by user and group, no access for others).

Failure to adhere to any of these requirements causes `mysql-proxy` to generate an error during startup.

The following tables list the supported configuration file and command-line options.

**Table 14.3. `mysql-proxy` Help Options**

Format	Option File	Description	Introduc- tion	Deprecated	Removed
<code>--help</code>	<code>help</code>	Show help options			
<code>--help-admin</code>	<code>help-admin</code>	Show admin module options			
<code>--help-all</code>	<code>help-all</code>	Show all help options			
<code>--help-proxy</code>	<code>help-proxy</code>	Show proxy module options			

**Table 14.4. `mysql-proxy` Admin Options**

Format	Option File	Description	Introduc- tion	Deprecated	Removed
<code>- -ad- min-ad- dress=host:port</code>	<code>admin-ad- dress=host:port</code>	The admin module listening host and port			
<code>- -ad- min- lua- script=file_name</code>	<code>admin- lua- script=file_name</code>	Script to execute by the admin module			
<code>- -ad- min-pass- word=password</code>	<code>admin-pass- word=password</code>	Authentication password for admin module			
<code>- -ad- min-user- name=user_name</code>	<code>admin-user- name=user_name</code>	Authentication user name for admin module			
<code>- - proxy-ad- dress=host:port</code>	<code>proxy-ad- dress=host:port</code>	The listening proxy server host and port			

**Table 14.5. `mysql-proxy` Proxy Options**

Format	Option File	Description	Introduc- tion	Deprecated	Removed
--no-proxy	no-proxy	Do not start the proxy module			
- - proxy-backend-ad- dresses=host:port	proxy-backend-ad- dresses=host:port	The MySQL server host and port			
- - proxy-fix-bug-25371	proxy-fix-bug-25371	Enable the fix for Bug #25371 for older libmysql versions			0.8.1
- - proxy-lua-script=file_name	proxy-lua-script=file_name	Filename for Lua script for proxy operations			
- - proxy-pool-no-change-user	proxy-pool-no-change-user	Do not use the protocol CHANGE_USER command to reset the connection when coming from the connection pool			
- - proxy-read-only-backend-ad- dresses=host:port	proxy-read-only-backend-ad- dresses=host:port	The MySQL server host and port (read only)			
- - proxy-skip-profiling	proxy-skip-profiling	Disable query profiling			

Table 14.6. `mysql-proxy` Applications Options

Format	Option File	Description	Introduc- tion	Deprecated	Removed
- -basedir=dir_name	basedir=dir_name	The base directory prefix for paths in the configuration			
--daemon	daemon	Start in daemon mode			
- -de-faults-file=file_name		The configuration file to use			
- - event-threads=count	event-threads=count	The number of event-handling threads			
--keepalive	keepalive	Try to restart the proxy if a crash occurs			
- - log-back-trace-on-crash	log-back-trace-on-crash	Try to invoke the debugger and generate a backtrace on crash			
- - log-file=file_name	log-file=file_name	The file where error messages are logged			

Format	Option File	Description	Introduc- tion	Deprecated	Removed
--log-level=level	log-level=level	The logging level			
--log-use-syslog	log-use-syslog	Log errors to syslog			
- - lua- cpath=dir_name	lua- cpath=dir_name	Set the LUA_CPATH			
- - lua-path=dir_name	lua-path=dir_name	Set the LUA_PATH			
- - max- open-files=count	max- open-files=count	The maximum number of open files to support			
- - pid-file=file_name	pid-file=file_name	File in which to store the process ID			
- -plu- gin-dir=dir_name	plugin- dir=dir_name	Directory containing plugin files			
- -plugins=plugin,...	plugins=plugin,...	List of plugins to load			
--user=user_name	user=user_name	The user to use when running mysql-proxy			
--version	version	Show version information			

Except as noted in the following details, all of the options can be used within the configuration file by supplying the option and the corresponding value. For example:

```
[mysql-proxy]
log-file = /var/log/mysql-proxy.log
log-level = message
```

- `--help, -h`

<b>Command-Line Format</b>	<code>--help</code>
	<code>-h</code>
<b>Option-File Format</b>	<code>help</code>

Show available help options.

- `--help-admin`

<b>Command-Line Format</b>	<code>--help-admin</code>
<b>Option-File Format</b>	<code>help-admin</code>

Show options for the admin module.

- `--help-all`

<b>Command-Line Format</b>	<code>--help-all</code>
<b>Option-File Format</b>	<code>help-all</code>

Show all help options.

- `--help-proxy`

<b>Command-Line Format</b>	<code>--help-proxy</code>
<b>Option-File Format</b>	<code>help-proxy</code>

Show options for the proxy module.

- `--admin-address=host:port`

<b>Command-Line Format</b>	<code>--admin-address=host:port</code>	
<b>Option-File Format</b>	<code>admin-address=host:port</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>:4041</code>

The host name (or IP address) and port for the administration port. The default is `localhost:4041`.

- `--admin-lua-script=file_name`

<b>Command-Line Format</b>	<code>--admin-lua-script=file_name</code>	
<b>Option-File Format</b>	<code>admin-lua-script=file_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	

The script to use for the proxy administration module.

- `--admin-password=password`

<b>Command-Line Format</b>	<code>--admin-password=password</code>	
<b>Option-File Format</b>	<code>admin-password=password</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	

The password to use to authenticate users wanting to connect to the MySQL Proxy administration module. This module uses the MySQL protocol to request a user name and password for connections.

- `--admin-username=user_name`

<b>Command-Line Format</b>	<code>--admin-username=user_name</code>	
<b>Option-File Format</b>	<code>admin-username=user_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>root</code>

The user name to use to authenticate users wanting to connect to the MySQL Proxy administration module. This module uses the MySQL protocol to request a user name and password for connections. The default user name is `root`.

- `--basedir=dir_name`

Command-Line Format	<code>--basedir=dir_name</code>	
Option-File Format	<code>basedir=dir_name</code>	
	Permitted Values	
	Type	directory name

The base directory to use as a prefix for all other file name configuration options. The base name should be an absolute (not relative) directory. If you specify a relative directory, `mysql-proxy` generates an error during startup.

- `--daemon`

Command-Line Format	<code>--daemon</code>	
Option-File Format	<code>daemon</code>	

Starts the proxy in daemon mode.

- `--defaults-file=file_name`

Command-Line Format	<code>--defaults-file=file_name</code>	
---------------------	--	--

The file to read for configuration options. If not specified, MySQL Proxy takes options only from the command line.

- `--event-threads=count`

Command-Line Format	<code>--event-threads=count</code>	
Option-File Format	<code>event-threads=count</code>	
	Permitted Values	
	Type	numeric
	Default	1

The number of event threads to reserve to handle incoming requests.

- `--keepalive`

Command-Line Format	<code>--keepalive</code>	
Option-File Format	<code>keepalive</code>	

Create a process surrounding the main `mysql-proxy` process that attempts to restart the main `mysql-proxy` process in the event of a crash or other failure.

### Note

The `--keepalive` option is not available on Microsoft Windows. When running as a service, `mysql-proxy` automatically restarts.

- `--log-backtrace-on-crash`

Command-Line Format	<code>--log-backtrace-on-crash</code>	
Option-File Format	<code>log-backtrace-on-crash</code>	

Log a backtrace to the error log and try to initialize the debugger in the event of a failure.

- `--log-file=file_name`

<b>Command-Line Format</b>	<code>--log-file=file_name</code>	
<b>Option-File Format</b>	<code>log-file=file_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The file to use to record log information. If this option is not given, `mysql-proxy` logs to the standard error output.

- `--log-level=level`

<b>Command-Line Format</b>	<code>--log-level=level</code>	
<b>Option-File Format</b>	<code>log-level=level</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Valid Values</b>	<code>error</code> <code>warning</code> <code>info</code> <code>message</code> <code>debug</code>

The log level to use when outputting error messages. Messages with that level (or lower) are output. For example, `message` level also outputs message with `info`, `warning`, and `error` levels.

- `--log-use-syslog`

<b>Command-Line Format</b>	<code>--log-use-syslog</code>	
<b>Option-File Format</b>	<code>log-use-syslog</code>	

Log errors to the syslog (Unix/Linux only).

- `--lua-cpath=dir_name`

<b>Command-Line Format</b>	<code>--lua-cpath=dir_name</code>	
<b>Option-File Format</b>	<code>lua-cpath=dir_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

The `LUA_CPATH` to use when loading compiled modules or libraries for Lua scripts.

- `--lua-path=dir_name`

<b>Command-Line Format</b>	<code>--lua-path=dir_name</code>	
<b>Option-File Format</b>	<code>lua-path=dir_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

The `LUA_CPATH` to use when loading modules for Lua.

- `--max-open-files=count`

<b>Command-Line Format</b>	<code>--max-open-files=count</code>	
<b>Option-File Format</b>	<code>max-open-files=count</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>

The maximum number of open files and sockets supported by the `mysql-proxy` process. Certain scripts might require a higher value.

- `--no-proxy`

<b>Command-Line Format</b>	<code>--no-proxy</code>	
<b>Option-File Format</b>	<code>no-proxy</code>	

Disable the proxy module.

- `--plugin-dir=dir_name`

<b>Command-Line Format</b>	<code>--plugin-dir=dir_name</code>	
<b>Option-File Format</b>	<code>plugin-dir=dir_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

The directory to use when loading plugins for `mysql-proxy`.

- `--plugins=plugin,...`

<b>Command-Line Format</b>	<code>--plugins=plugin,...</code>	
<b>Option-File Format</b>	<code>plugins=plugin,...</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

A comma-separated list of plugins to load.

- `--proxy-address=host:port, -P host:port`

<b>Command-Line Format</b>	<code>--proxy-address=host:port</code>	
	<code>-P host:port</code>	
<b>Option-File Format</b>	<code>proxy-address=host:port</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>:4040</code>

The listening host name (or IP address) and port of the proxy server. The default is `:4040` (all IPs on port 4040).

- `--proxy-read-only-backend-addresses=host:port, -r host:port`

<b>Command-Line Format</b>	<code>--proxy-read-only-backend-addresses=host:port</code>	
	<code>-r host:port</code>	
<b>Option-File Format</b>	<code>proxy-read-only-backend-addresses=host:port</code>	

	Permitted Values	
	Type	string

The listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.

### Note

Setting this value only configures the servers within the corresponding internal structure (see `proxy.global.backends`). You can determine the backend type by checking the `type` field for each connection.

You should therefore only use this option in combination with a script designed to make use of the different backend types.

When using this option on the command line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-read-only-backend-addresses 192.168.0.1:3306 --proxy-read-only-backend-addresses 192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers by commas. The equivalent of the preceding example would be:

```
...
proxy-read-only-backend-addresses = 192.168.0.1:3306,192.168.0.2:3306
```

- `--proxy-backend-addresses=host:port, -b host:port`

Command-Line Format	<code>--proxy-backend-addresses=host:port</code>	
	<code>-b host:port</code>	
Option-File Format	<code>proxy-backend-addresses=host:port</code>	
	Permitted Values	
	Type	string
	Default	127.0.0.1:3306

The host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.

When using this option on the command line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-backend-addresses 192.168.0.1:3306 --proxy-backend-addresses 192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers by commas. The equivalent of the preceding example would be:

```
...
proxy-backend-addresses = 192.168.0.1:3306,192.168.0.2:3306
```

- `--proxy-pool-no-change-user`

Command-Line Format	<code>--proxy-pool-no-change-user</code>
Option-File Format	<code>proxy-pool-no-change-user</code>

Disable use of the MySQL protocol `CHANGE_USER` command when reusing a connection from the pool of connections specified

by the `proxy-backend-addresses` list.

- `--proxy-skip-profiling`

<b>Command-Line Format</b>	<code>--proxy-skip-profiling</code>
<b>Option-File Format</b>	<code>proxy-skip-profiling</code>

Disable query profiling (statistics time tracking). The default is for tracking to be enabled.

- `--proxy-fix-bug-25371`

<b>Version Removed</b>	0.8.1
<b>Command-Line Format</b>	<code>--proxy-fix-bug-25371</code>
<b>Option-File Format</b>	<code>proxy-fix-bug-25371</code>

Enable a workaround for an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.

This option was removed in `mysql-proxy` 0.8.1. Now, `mysql-proxy` returns an error message at the protocol level if it sees a `COM_CHANGE_USER` being sent to a server that has a version from 5.1.14 to 5.1.17.

- `--proxy-lua-script=file_name, -s file_name`

<b>Command-Line Format</b>	<code>--proxy-lua-script=file_name</code>	
	<code>-s file_name</code>	
<b>Option-File Format</b>	<code>proxy-lua-script=file_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while `mysql-proxy` is running, the updated content is automatically used when a new connection is made.

- `--pid-file=file_name`

<b>Command-Line Format</b>	<code>--pid-file=file_name</code>	
<b>Option-File Format</b>	<code>pid-file=file_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The name of the file in which to store the process ID.

- `--user=user_name`

<b>Command-Line Format</b>	<code>--user=user_name</code>	
<b>Option-File Format</b>	<code>user=user_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

Run `mysql-proxy` as the specified `user`.

- `--version, -V`

<b>Command-Line Format</b>	<code>--version</code>
	<code>-V</code>
<b>Option-File Format</b>	<code>version</code>

Show the version number.

The most common usage is as a simple proxy service (that is, without additional scripting). For basic proxy operation, you must specify at least one `proxy-backend-addresses` option to specify the MySQL server to connect to by default:

```
shell> mysql-proxy --proxy-backend-addresses=MySQL.example.com:3306
```

The default proxy port is `4040`, so you can connect to your MySQL server through the proxy by specifying the host name and port details:

```
shell> mysql --host=localhost --port=4040
```

If your server requires authentication information, this will be passed through natively without alteration by `mysql-proxy`, so you must also specify the required authentication information:

```
shell> mysql --host=localhost --port=4040 \  
--user=user_name --password=password
```

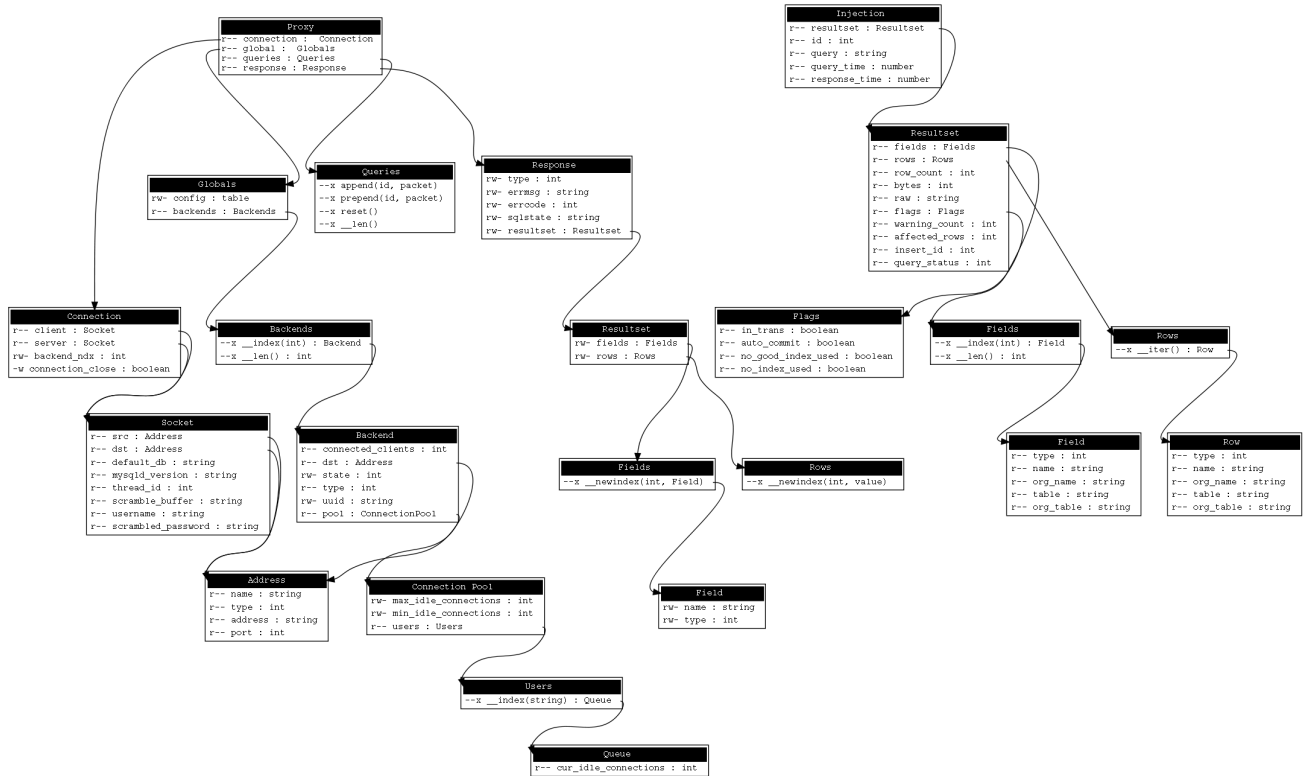

You can also connect to a read-only port (which filters out `UPDATE` and `INSERT` queries) by connecting to the read-only port. By default the host name is the default, and the port is `4042`, but you can alter the host/port information by using the `--proxy-read-only-backend-addresses` command-line option.

For more detailed information on how to use these command-line options, and `mysql-proxy` in general in combination with Lua scripts, see [Section 14.7.5, “Using MySQL Proxy”](#).

## 14.7.4. MySQL Proxy Scripting

You can control how MySQL Proxy manipulates and works with the queries and results that are passed on to the MySQL server through the use of the embedded Lua scripting language. You can find out more about the Lua programming language from the [Lua Web site](#).

The following diagram shows an overview of the classes exposed by MySQL Proxy.

The primary interaction between MySQL Proxy and the server is provided by defining one or more functions through an Lua script. A number of functions are supported, according to different events and operations in the communication sequence between a client and one or more backend MySQL servers:

- `connect_server()`: This function is called each time a connection is made to MySQL Proxy from a client. You can use this function during load-balancing to intercept the original connection and decide which server the client should ultimately be attached to. If you do not define a special solution, a simple round-robin style distribution is used by default.
- `read_handshake()`: This function is called when the initial handshake information is returned by the server. You can capture the handshake information returned and provide additional checks before the authorization exchange takes place.
- `read_auth()`: This function is called when the authorization packet (user name, password, default database) are submitted by the client to the server for authentication.
- `read_auth_result()`: This function is called when the server returns an authorization packet to the client indicating whether the authorization succeeded.
- `read_query()`: This function is called each time a query is sent by the client to the server. You can use this to edit and manipulate the original query, including adding new queries before and after the original statement. You can also use this function to return information directly to the client, bypassing the server, which can be useful to filter unwanted queries or queries that exceed known limits.
- `read_query_result()`: This function is called each time a result is returned from the server, providing you have manually injected queries into the query queue. If you have not explicitly injected queries within the `read_query()` function, this function is not triggered. You can use this to edit the result set, or to remove or filter the result sets generated from additional queries you injected into the queue when using `read_query()`.

The following table describes the direction of information flow at the point when the function is triggered.

Function	Supplied Information	Direction
<code>connect_server()</code>	None	Client to Server
<code>read_handshake()</code>	None	Server to Client

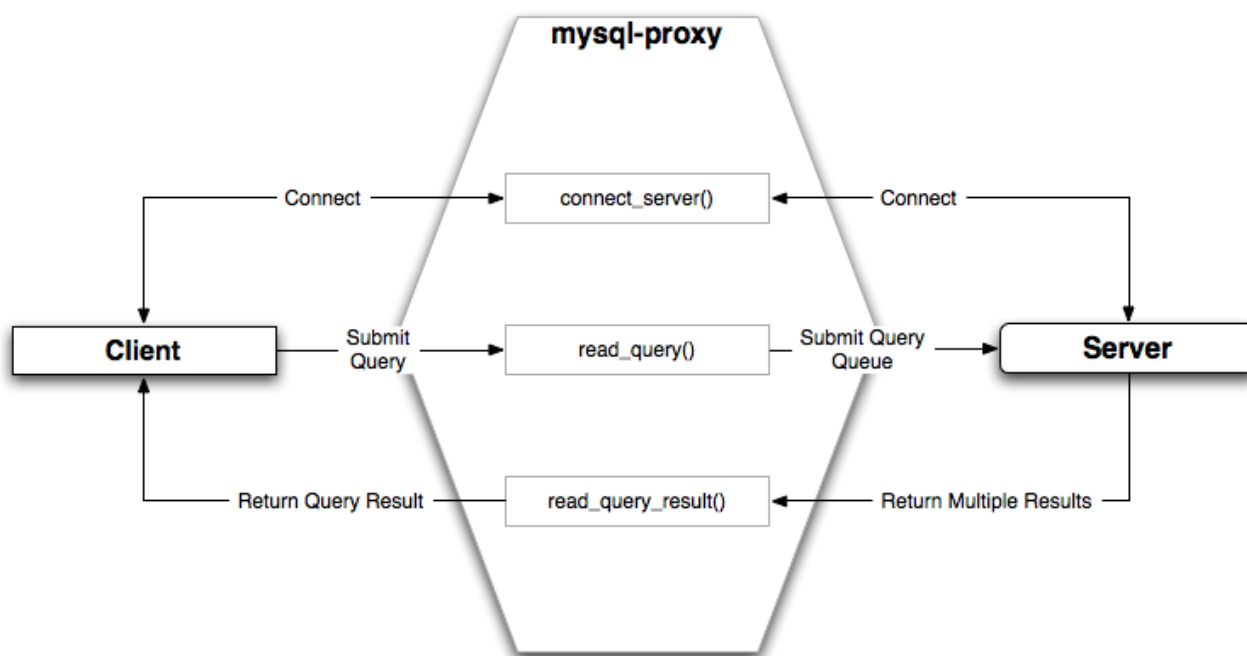

Function	Supplied Information	Direction
<code>read_auth()</code>	None	Client to Server
<code>read_auth_result()</code>	None	Server to Client
<code>read_query()</code>	Query	Client to Server
<code>read_query_result()</code>	Query result	Server to Client

By default, all functions return a result that indicates whether the data should be passed on to the client or server (depending on the direction of the information being transferred). This return value can be overridden by explicitly returning a constant indicating that a particular response should be sent. For example, it is possible to construct result set information by hand within `read_query()` and to return the result set directly to the client without ever sending the original query to the server.

In addition to these functions, a number of built-in structures provide control over how MySQL Proxy forwards queries and returns the results by providing a simplified interface to elements such as the list of queries and the groups of result sets that are returned.

#### 14.7.4.1. Proxy Scripting Sequence During Query Injection

The following figure gives an example of how the proxy might be used when injecting queries into the query queue. Because the proxy sits between the client and MySQL server, what the proxy sends to the server, and the information that the proxy ultimately returns to the client, need not match or correlate. Once the client has connected to the proxy, the sequence shown in the following diagram occurs for each individual query sent by the client.

1. When the client submits one query to the proxy, the `read_query()` function within the proxy is triggered. The function adds the query to the query queue.
2. Once manipulation by `read_query()` has completed, the queries are submitted, sequentially, to the MySQL server.
3. The MySQL server returns the results from each query, one result set for each query submitted. The `read_query_result()` function is triggered for each result set, and each invocation can decide which result set to return to the client

For example, you can queue additional queries into the global query queue to be processed by the server. This can be used to add statistical information by adding queries before and after the original query, changing the original query:

```
SELECT * FROM City;
```

Into a sequence of queries:

```
SELECT NOW();
SELECT * FROM City;
SELECT NOW();
```

You can also modify the original statement; for example, to add `EXPLAIN` to each statement executed to get information on how the statement was processed, again altering our original SQL statement into a number of statements:

```
SELECT * FROM City;
EXPLAIN SELECT * FROM City;
```

In both of these examples, the client would have received more result sets than expected. Regardless of how you manipulate the incoming query and the returned result, the number of queries returned by the proxy must match the number of original queries sent by the client.

You could adjust the client to handle the multiple result sets sent by the proxy, but in most cases you will want the existence of the proxy to remain transparent. To ensure that the number of queries and result sets match, you can use the MySQL Proxy `read_query_result()` to extract the additional result set information and return only the result set the client originally requested back to the client. You can achieve this by giving each query that you add to the query queue a unique ID, then filter out queries that do not match the original query ID when processing them with `read_query_result()`.

### 14.7.4.2. Internal Structures

There are a number of internal structures within the scripting element of MySQL Proxy. The primary structure is `proxy` and this provides an interface to the many common structures used throughout the script, such as connection lists and configured backend servers. Other structures, such as the incoming packet from the client and result sets are only available within the context of one of the scriptable functions.

Attribute	Description
<code>connection</code>	A structure containing the active client connections. For a list of attributes, see <code>proxy.connection</code> .
<code>servers</code>	A structure containing the list of configured backend servers. For a list of attributes, see <code>proxy.global.backends</code> .
<code>queries</code>	A structure containing the queue of queries that will be sent to the server during a single client query. For a list of attributes, see <code>proxy.queries</code> .
<code>PROXY_VERSION</code>	The version number of MySQL Proxy, encoded in hex. You can use this to check that the version number supports a particular option from within the Lua script. Note that the value is encoded as a hex value, so to check the version is at least 0.5.1 you compare against <code>0x00501</code> .

#### `proxy.connection`

The `proxy.connection` object is read only, and provides information about the current connection, and is split into a `client` and `server` tables. This enables you to examine information about both the incoming client connections to the proxy (`client`), and to the backend servers (`server`).

Attribute	Description
<code>client.default_db</code>	Default database requested by the client
<code>client.username</code>	User name used to authenticate
<code>client.scrambled_password</code>	The scrambled version of the password used to authenticate
<code>client.dst.name</code>	The combined <code>address:port</code> of the Proxy port used by this client (should match the <code>--proxy-address</code> configuration parameter)
<code>client.dst.address</code>	The IP address of the of the Proxy port used by this client
<code>client.dst.port</code>	The port number of the of the Proxy port used by this client
<code>client.src.name</code>	The combined <code>address:port</code> of the client (originating) TCP/IP endpoint
<code>client.src.address</code>	The IP address of the client (originating) TCP/IP port
<code>client.src.port</code>	The port of the client (originating) TCP/IP endpoint

Attribute	Description
<code>server.scramble_buffer</code>	The scramble buffer used to scramble the password
<code>server.mysql_d_version</code>	The MySQL version number of the server
<code>server.thread_id</code>	The ID of the thread handling the connection to the current server
<code>server.dst.name</code>	The combined <code>address:port</code> for the backend server for the current connection (i.e. the connection to the MySQL server)
<code>server.dst.address</code>	The address for the backend server
<code>server.dst.port</code>	The port for the backend server
<code>server.src.name</code>	The combined <code>address:port</code> for the TCP/IP endpoint used by the Proxy to connect to the backend server
<code>server.src.address</code>	The address of the endpoint for the proxy-side connection to the MySQL server
<code>server.src.port</code>	The port of the endpoint for the proxy-side connection to the MySQL server

### `proxy.global.backends`

The `proxy.global.backends` table is partially writable and contains an array of all the configured backend servers and the server metadata (IP address, status, etc.). You can determine the array index of the current connection using `proxy.connection["backend_ndx"]` which is the index into this table of the backend server being used by the active connection.

The attributes for each entry within the `proxy.global.backends` table are shown in this table.

Attribute	Description
<code>dst.name</code>	The combined <code>address:port</code> of the backend server.
<code>dst.address</code>	The IP address of the backend server.
<code>dst.port</code>	The port of the backend server.
<code>connected_clients</code>	The number of clients currently connected.
<code>state</code>	The status of the backend server. See <a href="#">Backend State/Type Constants [1522]</a>
<code>type</code>	The type of the backend server. You can use this to identify whether the backend was configured as a standard read/write backend, or a read-only backend. You can compare this value to the <code>proxy.BACKEND_TYPE_RW</code> and <code>proxy.BACKEND_TYPE_RO</code> .

### `proxy.queries`

The `proxy.queries` object is a queue representing the list of queries to be sent to the server. The queue is not populated automatically, but if you do not explicitly populate the queue, queries are passed on to the backend server verbatim. Also, if you do not populate the query queue by hand, the `read_query_result()` function is not triggered.

The following methods are supported for populating the `proxy.queries` object.

Function	Description
<code>append(id,packet,[options])</code>	Appends a query to the end of the query queue. The <code>id</code> is an integer identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet. The optional <code>options</code> should be a table containing the options specific to this packet.
<code>prepend(id,packet)</code>	Prepends a query to the query queue. The <code>id</code> is an identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.
<code>reset()</code>	Empties the query queue.
<code>len()</code>	Returns the number of query packets in the queue.

For example, you could append a query packet to the `proxy.queries` queue by using the `append()`:

```
proxy.queries:append(1,packet)
```

The optional third argument to `append()` should contain the options for the packet. To have access to the result set through the `read_query_result()` function, set the `resultset_is_needed` flag to `true`:

```
proxy.queries:append( 1, packet, { resultset_is_needed = true } )
```

If that flag is `false` (the default), proxy will:

- Send the result set to the client as soon as it is received
- Reduce memory usage (because the result set is not stored internally for processing)
- Reduce latency of returning results to the client
- Pass data from server to client unaltered

The default mode is therefore quicker and useful if you only want to monitor the queries sent, and the basic statistics.

To perform any kind of manipulation on the returned data, you must set the flag to `true`, which will:

- Store the result set so that it can be processed.
- Enable modification of the result set before it is returned to the client.
- Enable you to discard the result set instead of returning it to the client.

### proxy.response

The `proxy.response` structure is used when you want to return your own MySQL response, instead of forwarding a packet that you have received a backend server. The structure holds the response type information, an optional error message, and the result set (rows/columns) to return.

Attribute	Description
<code>type</code>	The type of the response. The type must be either <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code> . If the <code>MYSQLD_PACKET_ERR</code> , you should set the value of the <code>mysql.response.errmsg</code> with a suitable error message.
<code>errmsg</code>	A string containing the error message that will be returned to the client.
<code>resultset</code>	A structure containing the result set information (columns and rows), identical to what would be returned when returning a results from a <code>SELECT</code> query.

When using `proxy.response` you either set `proxy.response.type` to `proxy.MYSQLD_PACKET_OK` and then build `resultset` to contain the results to return, or set `proxy.response.type` to `proxy.MYSQLD_PACKET_ERR` and set the `proxy.response.errmsg` to a string with the error message. To send the completed result set or error message, you should return the `proxy.PROXY_SEND_RESULT` to trigger the return of the packet information.

An example of this can be seen in the `tutorial-resultset.lua` script within the MySQL Proxy package:

```
if string.lower(command) == "show" and string.lower(option) == "querycounter" then
    ---
    -- proxy.PROXY_SEND_RESULT requires
    --
    -- proxy.response.type to be either
    -- * proxy.MYSQLD_PACKET_OK or
    -- * proxy.MYSQLD_PACKET_ERR
    --
    -- for proxy.MYSQLD_PACKET_OK you need a resultset
    -- * fields
    -- * rows
    --
    -- for proxy.MYSQLD_PACKET_ERR
    -- * errmsg
    proxy.response.type = proxy.MYSQLD_PACKET_OK
```

```

    proxy.response.resultset = {
        fields = {
            { type = proxy.MYSQL_TYPE_LONG, name = "global_query_counter", },
            { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
        },
        rows = {
            { proxy.global.query_counter, query_counter }
        }
    }

    -- we have our result, send it back
    return proxy.PROXY_SEND_RESULT
elseif string.lower(command) == "show" and string.lower(option) == "myerror" then
    proxy.response.type = proxy.MYSQLD_PACKET_ERR
    proxy.response.errmsg = "my first error"

    return proxy.PROXY_SEND_RESULT

```

### proxy.response.resultset

The `proxy.response.resultset` structure should be populated with the rows and columns of data to return. The structure contains the information about the entire result set, with the individual elements of the data shown in the following table.

Attribute	Description
<code>fields</code>	The definition of the columns being returned. This should be a dictionary structure with the <code>type</code> specifying the MySQL data type, and the <code>name</code> specifying the column name. Columns should be listed in the order of the column data that will be returned.
<code>flags</code>	A number of flags related to the result set. Valid flags include <code>auto_commit</code> (whether an automatic commit was triggered), <code>no_good_index_used</code> (the query executed without using an appropriate index), and <code>no_index_used</code> (the query executed without using any index).
<code>rows</code>	The actual row data. The information should be returned as an array of arrays. Each inner array should contain the column data, with the outer array making up the entire result set.
<code>warning_count</code>	The number of warnings for this result set.
<code>affected_rows</code>	The number of rows affected by the original statement.
<code>insert_id</code>	The last insert ID for an auto-incremented column in a table.
<code>query_status</code>	The status of the query operation. You can use the <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code> constants to populate this parameter.

For an example showing how to use this structure, see `proxy.response`.

### Proxy Return State Constants

The following constants are used internally by the proxy to specify the response to send to the client or server. All constants are exposed as values within the main `proxy` table.

Constant	Description
<code>PROXY_SEND_QUERY</code>	Causes the proxy to send the current contents of the queries queue to the server.
<code>PROXY_SEND_RESULT</code>	Causes the proxy to send a result set back to the client.
<code>PROXY_IGNORE_RESULT</code>	Causes the proxy to drop the result set (nothing is returned to the client).

As constants, these entities are available without qualification in the Lua scripts. For example, at the end of the `read_query_result()` you might return `PROXY_IGNORE_RESULT`:

```
return proxy.PROXY_IGNORE_RESULT
```

### Packet State Constants

The following states describe the status of a network packet. These items are entries within the main `proxy` table.

Constant	Description
<code>MYSQLD_PACKET_OK</code>	The packet is OK
<code>MYSQLD_PACKET_ERR</code>	The packet contains error information
<code>MYSQLD_PACKET_RAW</code>	The packet contains raw data

### Backend State/Type Constants

The following constants are used either to define the status or type of the backend MySQL server to which the proxy is connected. These items are entries within the main `proxy` table.

Constant	Description
<code>BACKEND_STATE_UNKNOWN</code>	The current status is unknown
<code>BACKEND_STATE_UP</code>	The backend is known to be up (available)
<code>BACKEND_STATE_DOWN</code>	The backend is known to be down (unavailable)
<code>BACKEND_TYPE_UNKNOWN</code>	Backend type is unknown
<code>BACKEND_TYPE_RW</code>	Backend is available for read/write
<code>BACKEND_TYPE_RO</code>	Backend is available only for read-only use

### Server Command Constants

The following values are used in the packets exchanged between the client and server to identify the information in the rest of the packet. These items are entries within the main `proxy` table. The packet type is defined as the first character in the sent packet. For example, when intercepting packets from the client to edit or monitor a query, you would check that the first byte of the packet was of type `proxy.COM_QUERY`.

Constant	Description
<code>COM_SLEEP</code>	Sleep
<code>COM_QUIT</code>	Quit
<code>COM_INIT_DB</code>	Initialize database
<code>COM_QUERY</code>	Query
<code>COM_FIELD_LIST</code>	Field List
<code>COM_CREATE_DB</code>	Create database
<code>COM_DROP_DB</code>	Drop database
<code>COM_REFRESH</code>	Refresh
<code>COM_SHUTDOWN</code>	Shutdown
<code>COM_STATISTICS</code>	Statistics
<code>COM_PROCESS_INFO</code>	Process List
<code>COM_CONNECT</code>	Connect
<code>COM_PROCESS_KILL</code>	Kill
<code>COM_DEBUG</code>	Debug
<code>COM_PING</code>	Ping
<code>COM_TIME</code>	Time
<code>COM_DELAYED_INSERT</code>	Delayed insert
<code>COM_CHANGE_USER</code>	Change user
<code>COM_BINLOG_DUMP</code>	Binlog dump
<code>COM_TABLE_DUMP</code>	Table dump
<code>COM_CONNECT_OUT</code>	Connect out
<code>COM_REGISTER_SLAVE</code>	Register slave

Constant	Description
<a href="#">COM_STMT_PREPARE</a>	Prepare server-side statement
<a href="#">COM_STMT_EXECUTE</a>	Execute server-side statement
<a href="#">COM_STMT_SEND_LONG_DATA</a>	Long data
<a href="#">COM_STMT_CLOSE</a>	Close server-side statement
<a href="#">COM_STMT_RESET</a>	Reset statement
<a href="#">COM_SET_OPTION</a>	Set option
<a href="#">COM_STMT_FETCH</a>	Fetch statement
<a href="#">COM_DAEMON</a>	Daemon (MySQL 5.1 only)
<a href="#">COM_ERROR</a>	Error

### MySQL Type Constants

These constants are used to identify the field types in the query result data returned to clients from the result of a query. These items are entries within the main [proxy](#) table.

Constant	Field Type
<a href="#">MYSQL_TYPE_DECIMAL</a>	Decimal
<a href="#">MYSQL_TYPE_NEWDECIMAL</a>	Decimal (MySQL 5.0 or later)
<a href="#">MYSQL_TYPE_TINY</a>	Tiny
<a href="#">MYSQL_TYPE_SHORT</a>	Short
<a href="#">MYSQL_TYPE_LONG</a>	Long
<a href="#">MYSQL_TYPE_FLOAT</a>	Float
<a href="#">MYSQL_TYPE_DOUBLE</a>	Double
<a href="#">MYSQL_TYPE_NULL</a>	Null
<a href="#">MYSQL_TYPE_TIMESTAMP</a>	Timestamp
<a href="#">MYSQL_TYPE_LONGLONG</a>	Long long
<a href="#">MYSQL_TYPE_INT24</a>	Integer
<a href="#">MYSQL_TYPE_DATE</a>	Date
<a href="#">MYSQL_TYPE_TIME</a>	Time
<a href="#">MYSQL_TYPE_DATETIME</a>	Datetime
<a href="#">MYSQL_TYPE_YEAR</a>	Year
<a href="#">MYSQL_TYPE_NEWDATE</a>	Date (MySQL 5.0 or later)
<a href="#">MYSQL_TYPE_ENUM</a>	Enumeration
<a href="#">MYSQL_TYPE_SET</a>	Set
<a href="#">MYSQL_TYPE_TINY_BLOB</a>	Tiny Blob
<a href="#">MYSQL_TYPE_MEDIUM_BLOB</a>	Medium Blob
<a href="#">MYSQL_TYPE_LONG_BLOB</a>	Long Blob
<a href="#">MYSQL_TYPE_BLOB</a>	Blob
<a href="#">MYSQL_TYPE_VAR_STRING</a>	Varstring
<a href="#">MYSQL_TYPE_STRING</a>	String
<a href="#">MYSQL_TYPE_TINY</a>	Tiny (compatible with <a href="#">MYSQL_TYPE_CHAR</a> )
<a href="#">MYSQL_TYPE_ENUM</a>	Enumeration (compatible with <a href="#">MYSQL_TYPE_INTERVAL</a> )
<a href="#">MYSQL_TYPE_GEOMETRY</a>	Geometry
<a href="#">MYSQL_TYPE_BIT</a>	Bit

### 14.7.4.3. Capturing a Connection with `connect_server()`

When the proxy accepts a connection from a MySQL client, the `connect_server()` function is called.

There are no arguments to the function, but you can use and if necessary manipulate the information in the `proxy.connection` table, which is unique to each client session.

For example, if you have multiple backend servers, you can specify which server that connection should use by setting the value of `proxy.connection.backend_ndx` to a valid server number. The following code chooses between two servers based on whether the current time in minutes is odd or even:

```
function connect_server()
  print("--> a client really wants to talk to a server")
  if (tonumber(os.date("%M")) % 2 == 0) then
    proxy.connection.backend_ndx = 2
    print("Choosing backend 2")
  else
    proxy.connection.backend_ndx = 1
    print("Choosing backend 1")
  end
  print("Using " .. proxy.global.backends[proxy.connection.backend_ndx].dst.name)
end
```

This example also displays the IP address/port combination by accessing the information from the internal `proxy.global.backends` table.

### 14.7.4.4. Examining the Handshake with `read_handshake()`

Handshake information is sent by the server to the client after the initial connection (through `connect_server()`) has been made. The handshake information contains details about the MySQL version, the ID of the thread that will handle the connection information, and the IP address of the client and server. This information is exposed through the `proxy.connection` structure.

- `proxy.connection.server.mysql_version`: The version of the MySQL server.
- `proxy.connection.server.thread_id`: The thread ID.
- `proxy.connection.server.scramble_buffer`: The password scramble buffer.
- `proxy.connection.server.dst.name`: The IP address of the server.
- `proxy.connection.client.src.name`: The IP address of the client.

For example, you can print out the handshake data and refuse clients by IP address with the following function:

```
function read_handshake()
  print("<-- let's send him some information about us")
  print("  mysql-version: " .. proxy.connection.server.mysql_version)
  print("  thread-id      : " .. proxy.connection.server.thread_id)
  print("  scramble-buf   : " .. string.format("%q", proxy.connection.server.scramble_buffer))
  print("  server-addr    : " .. proxy.connection.server.dst.name)
  print("  client-addr    : " .. proxy.connection.client.src.name)

  if not proxy.connection.client.src.name:match("^127.0.0.1:") then
    proxy.response.type = proxy.MYSQLD_PACKET_ERR
    proxy.response.errmsg = "only local connects are allowed"

    print("we don't like this client");

    return proxy.PROXY_SEND_RESULT
  end
end
```

Note that you must return an error packet to the client by using `proxy.PROXY_SEND_RESULT`.

### 14.7.4.5. Examining the Authentication Credentials with `read_auth()`

The `read_auth()` function is triggered when an authentication handshake is initiated by the client. In the execution sequence, `read_auth()` occurs immediately after `read_handshake()`, so the server selection has already been made, but the connection and authorization information has not yet been provided to the backend server.

You can obtain the authentication information by examining the `proxy.connection.client` structure. For more information, see [proxy.connection](#).

For example, you can print the user name and password supplied during authorization using:

```
function read_auth()  
    print("    username    : " .. proxy.connection.client.username)  
    print("    password   : " .. string.format("%q", proxy.connection.client.scrambled_password))  
end
```

You can interrupt the authentication process within this function and return an error packet back to the client by constructing a new packet and returning `proxy.PROXY_SEND_RESULT`:

```
proxy.response.type = proxy.MYSQLD_PACKET_ERR  
proxy.response.errmsg = "Logins are not allowed"  
return proxy.PROXY_SEND_RESULT
```

#### 14.7.4.6. Accessing Authentication Information with `read_auth_result()`

The return packet from the server during authentication is captured by `read_auth_result()`. The only argument to this function is the authentication packet returned by the server. As the packet is a raw MySQL network protocol packet, you must access the first byte to identify the packet type and contents. The `MYSQLD_PACKET_ERR` and `MYSQLD_PACKET_OK` constants can be used to identify whether the authentication was successful:

```
function read_auth_result(auth)  
    local state = auth.packet:byte()  
  
    if state == proxy.MYSQLD_PACKET_OK then  
        print("<-- auth ok");  
    elseif state == proxy.MYSQLD_PACKET_ERR then  
        print("<-- auth failed");  
    else  
        print("<-- auth ... don't know: " .. string.format("%q", auth.packet));  
    end  
end
```

If a long-password capable client tries to authenticate to a server that supports long passwords, but the user password provided is actually short, `read_auth_result()` will be called twice. The first time, `auth.packet:byte()` will equal 254, indicating that the client should try again using the old password protocol. The second time `read_auth_result()` is called, `auth.packet:byte()` will indicate whether the authentication actually succeeded.

#### 14.7.4.7. Manipulating Queries with `read_query()`

The `read_query()` function is called once for each query submitted by the client and accepts a single argument, the query packet that was provided. To access the content of the packet, you must parse the packet contents manually.

For example, you can intercept a query packet and print out the contents using the following function definition:

```
function read_query( packet )  
    if packet:byte() == proxy.COM_QUERY then  
        print("we got a normal query: " .. packet:sub(2))  
    end  
end
```

This example checks the first byte of the packet to determine the type. If the type is `COM_QUERY` (see [Server Command Constants \[1522\]](#)), we extract the query from the packet and print it. The structure of the packet type supplied is important. In the case of a `COM_QUERY` packet, the remaining contents of the packet are the text of the query string. In this example, no changes have been made to the query or the list of queries that will ultimately be sent to the MySQL server.

To modify a query, or add new queries, you must populate the query queue (`proxy.queries`), then execute the queries that you have placed into the queue. If you do not modify the original query or the queue, the query received from the client is sent to the MySQL server verbatim.

When adding queries to the queue, you should follow these guidelines:

- The packets inserted into the queue must be valid query packets. For each packet, you must set the initial byte to the packet type. If you are appending a query, you can append the query statement to the rest of the packet.

- Once you add a query to the queue, the queue is used as the source for queries sent to the server. If you add a query to the queue to add more information, you must also add the original query to the queue or it will not be executed.
- Once the queue has been populated, you must set the return value from `read_query()` to indicate whether the query queue should be sent to the server.
- When you add queries to the queue, you should add an ID. The ID you specify is returned with the result set so that you identify each query and corresponding result set. The ID has no other purpose than as an identifier for correlating the query and result set. When operating in a passive mode, during profiling for example, you identify the original query and the corresponding result set so that the results expected by the client can be returned correctly.
- Unless your client is designed to cope with more result sets than queries, you should ensure that the number of queries from the client match the number of results sets returned to the client. Using the unique ID and removing result sets you inserted will help.

Normally, the `read_query()` and `read_query_result()` function are used in conjunction with each other to inject additional queries and remove the additional result sets. However, `read_query_result()` is only called if you populate the query queue within `read_query()`.

#### 14.7.4.8. Manipulating Results with `read_query_result()`

The `read_query_result()` is called for each result set returned by the server only if you have manually injected queries into the query queue. If you have not manipulated the query queue, this function is not called. The function supports a single argument, the result packet, which provides a number of properties:

- `id`: The ID of the result set, which corresponds to the ID that was set when the query packet was submitted to the server when using `append(id)` on the query queue. You must have set the `resultset_is_needed` flag to `append` to intercept the result set before it is returned to the client. See [proxy.queries \[1519\]](#).
- `query`: The text of the original query.
- `query_time`: The number of microseconds required to receive the first row of a result set since the query was sent to the server.
- `response_time`: The number of microseconds required to receive the last row of the result set since the query was sent to the server.
- `resultset`: The content of the result set data.

By accessing the result information from the MySQL server, you can extract the results that match the queries that you injected, return different result sets (for example, from a modified query), and even create your own result sets.

The following Lua script, for example, will output the query, followed by the query time and response time (that is, the time to execute the query and the time to return the data for the query) for each query sent to the server:

```
function read_query( packet )
    if packet:byte() == proxy.COM_QUERY then
        print("we got a normal query: " .. packet:sub(2))

        proxy.queries:append(1, packet )

        return proxy.PROXY_SEND_QUERY
    end
end

function read_query_result(inj)
    print("query-time: " .. (inj.query_time / 1000) .. "ms")
    print("response-time: " .. (inj.response_time / 1000) .. "ms")
end
```

You can access the rows of returned results from the result set by accessing the `rows` property of the `resultset` property of the result that is exposed through `read_query_result()`. For example, you can iterate over the results showing the first column from each row using this Lua fragment:

```
for row in inj.resultset.rows do
    print("injected query returned: " .. row[1])
end
```

Just like `read_query()`, `read_query_result()` can return different values for each result according to the result returned. If you have injected additional queries into the query queue, for example, remove the results returned from those additional queries and return only the results from the query originally submitted by the client.

The following example injects additional `SELECT NOW()` statements into the query queue, giving them a different ID to the ID of the original query. Within `read_query_result()`, if the ID for the injected queries is identified, we display the result row, and return the `proxy.PROXY_IGNORE_RESULT` from the function so that the result is not returned to the client. If the result is from any other query, we print out the query time information for the query and return the default, which passes on the result set unchanged. We could also have explicitly returned `proxy.PROXY_IGNORE_RESULT` to the MySQL client.

```
function read_query( packet )
    if packet:byte() == proxy.COM_QUERY then
        proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_needed = true} )
        proxy.queries:append(1, packet, {resultset_is_needed = true})
        proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_needed = true} )
    end
    return proxy.PROXY_SEND_QUERY
end

function read_query_result(inj)
    if inj.id == 2 then
        for row in inj.resultset.rows do
            print("injected query returned: " .. row[1])
        end
        return proxy.PROXY_IGNORE_RESULT
    else
        print("query-time: " .. (inj.query_time / 1000) .. "ms")
        print("response-time: " .. (inj.response_time / 1000) .. "ms")
    end
end
```

For further examples, see [Section 14.7.5, “Using MySQL Proxy”](#).

## 14.7.5. Using MySQL Proxy

There are a number of different ways to use MySQL Proxy. At the most basic level, you can allow MySQL Proxy to pass queries from clients to a single server. To use MySQL Proxy in this mode, you just have to specify on the command line the backend server to which the proxy should connect:

```
shell> mysql-proxy --proxy-backend-addresses=sakila:3306
```

If you specify multiple backend MySQL servers, the proxy connects each client to each server in a round-robin fashion. Suppose that you have two MySQL servers, A and B. The first client to connect is connected to server A, the second to server B, the third to server A. For example:

```
shell> mysql-proxy \
--proxy-backend-addresses=narcissus:3306 \
--proxy-backend-addresses=nostromo:3306
```

When you specify multiple servers in this way, the proxy automatically identifies when a MySQL server has become unavailable and marks it accordingly. New connections are automatically attached to a server that is available, and a warning is reported to the standard output from `mysql-proxy`:

```
network-mysqld.c.367: connect(nostromo:3306) failed: Connection refused
network-mysqld-proxy.c.2405: connecting to backend (nostromo:3306) failed, marking it as down for ...
```

Lua scripts enable a finer level of control, both over the connections and their distribution and how queries and result sets are processed. When using an Lua script, you must specify the name of the script on the command line using the `--proxy-lua-script` option:

```
shell> mysql-proxy --proxy-lua-script=mc.lua --proxy-backend-addresses=sakila:3306
```

When you specify a script, the script is not executed until a connection is made. This means that faults with the script are not raised until the script is executed. Script faults will not affect the distribution of queries to backend MySQL servers.

### Note

Because a script is not read until the connection is made, you can modify the contents of the Lua script file while the proxy

is still running and the modified script is automatically used for the next connection. This ensures that MySQL Proxy remains available because it need not be restarted for the changes to take effect.

### 14.7.5.1. Using the Administration Interface

The `mysql-proxy` administration interface can be accessed using any MySQL client using the standard protocols. You can use the administration interface to gain information about the proxy server as a whole - standard connections to the proxy are isolated to operate as if you were connected directly to the backend MySQL server.

In `mysql-proxy` 0.8.0 and earlier, a rudimentary interface was built into the proxy. In later versions this was replaced so that you must specify an administration script to be used when users connect to the administration interface.

To use the administration interface, specify the user name and password required to connect to the admin service, using the `--admin-username` and `--admin-password` options. You must also specify the Lua script to be used as the interface to the administration service by using the `admin-lua-script` script option to point to a Lua script.

For example, you can create a basic interface to the internal components of the `mysql-proxy` system using the following script, written by Diego Medina:

```

proxy.global.query_counter = proxy.global.query_counter or 0

function proxy.global.initialize_process_table()
    if proxy.global.process == nil then
        proxy.global.process = {}
    end
end

```

```

    if proxy.global.process[proxy.connection.server.thread_id] == nil then
        proxy.global.process[proxy.connection.server.thread_id] = {}
    end
end

function read_auth_result( auth )
    local state = auth.packet:byte()
    if state == proxy.MYSQLD_PACKET_OK then
        proxy.global.initialize_process_table()
        table.insert( proxy.global.process[proxy.connection.server.thread_id],
            { ip = proxy.connection.client.src.name, ts = os.time() } )
    end
end

function disconnect_client()
    local connection_id = proxy.connection.server.thread_id
    if connection_id then
        -- client has disconnected, set this to nil
        proxy.global.process[connection_id] = nil
    end
end

---
-- read_query() can return a resultset
--
-- You can use read_query() to return a result-set.
--
-- @param packet the mysql-packet sent by the client
--
-- @return
-- * nothing to pass on the packet as is,
-- * proxy.PROXY_SEND_QUERY to send the queries from the proxy.queries queue
-- * proxy.PROXY_SEND_RESULT to send your own result-set
--
function read_query( packet )
    -- a new query came in in this connection
    -- using proxy.global.* to make it available to the admin plugin
    proxy.global.query_counter = proxy.global.query_counter + 1
end

```

To use the script, save the first script to a file (`admin.lua` in the following example) and the other to `reporter.lua`, then run `mysql-proxy` specifying the admin script and a backend MySQL server:

```

shell> mysql-proxy --admin-lua-script=admin.lua --admin-password=password \ »
--admin-username=root --proxy-backend-addresses=127.0.0.1:3306 -proxy-lua-script=reporter.lua

```

In a different window, connect to the MySQL server through the proxy:

```

shell> mysql --user=root --password=password --port=4040
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1798669
Server version: 5.0.70-log Gentoo Linux mysql-5.0.70-r1

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>

```

In another different window, connect to the `mysql-proxy` admin service using the specified user name and password:

```

shell> mysql --user=root --password=password --port=4041 --host=localhost
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1
Server version: 5.0.99-agent-admin

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>

```

To monitor the status of the proxy, ask for a list of the current active processes:

```

mysql> show proxy processlist;
+-----+-----+-----+
| Id      | IP Address          | Time                |
+-----+-----+-----+
| 1798669 | 192.168.0.112:52592 | Wed Jan 20 16:58:00 2010 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql>

```

For more information on the example, see [MySQL Proxy Admin Example](#).

## 14.7.6. MySQL Proxy FAQ

### Questions

- [15.7.6.1](#): In load balancing, how can I separate reads from writes?
- [15.7.6.2](#): How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.
- [15.7.6.3](#): Can I use MySQL Proxy with all versions of MySQL?
- [15.7.6.4](#): Can I run MySQL Proxy as a daemon?
- [15.7.6.5](#): Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?
- [15.7.6.6](#): With load balancing, what happens to transactions? Are all queries sent to the same server?
- [15.7.6.7](#): Is it possible to use MySQL Proxy with updating a Lucene index (or Solr) by making TCP calls to that server to update?
- [15.7.6.8](#): Is the system context switch expensive, how much overhead does the Lua script add?
- [15.7.6.9](#): How much latency does a proxy add to a connection?

## Questions and Answers

### 15.7.6.1: In load balancing, how can I separate reads from writes?

There is no automatic separation of queries that perform reads or writes to the different backend servers. However, you can specify to [mysql-proxy](#) that one or more of the “backend” MySQL servers are read only.

```
shell> mysql-proxy \  
--proxy-backend-addresses=10.0.1.2:3306 \  
--proxy-read-only-backend-addresses=10.0.1.3:3306 &
```

### 15.7.6.2: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.

Specify the path to the socket:

```
--proxy-backend-addresses=/path/to/socket
```

### 15.7.6.3: Can I use MySQL Proxy with all versions of MySQL?

MySQL Proxy is designed to work with MySQL 5.0 or higher, and supports the MySQL network protocol for 5.0 and higher.

### 15.7.6.4: Can I run MySQL Proxy as a daemon?

Use the [--daemon](#) option. To keep track of the process ID, the daemon can be started with the [--pid-file=file](#) option to save the PID to a known file name. On version 0.5.x, the Proxy cannot be started natively as a daemon.

### 15.7.6.5: Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?

You can run the proxy on the application server, on its own box, or on the DB-server depending on the use case.

### 15.7.6.6: With load balancing, what happens to transactions? Are all queries sent to the same server?

Without any special customization the whole connection is sent to the same server. That keeps the whole connection state intact.

### 15.7.6.7: Is it possible to use MySQL Proxy with updating a Lucene index (or Solr) by making TCP calls to that server to update?

Yes, but it is not advised for now.

### 15.7.6.8: Is the system context switch expensive, how much overhead does the Lua script add?

Lua is fast and the overhead should be small enough for most applications. The raw packet overhead is around 400 microseconds.

### 15.7.6.9: How much latency does a proxy add to a connection?

In the range of 400 microseconds per request.

### 15.7.6.10: Do you have to make one large script and call it at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?

You can just change the script and the proxy will reload it when a client connects.

### 15.7.6.11: If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform

optimally?

MySQL Proxy can live on any box: application, database, or its own box. MySQL Proxy uses comparatively little CPU or RAM, with negligible additional requirements or overhead.

**15.7.6.12: I currently use SQL Relay for efficient connection pooling with a number of Apache processes connecting to a MySQL server. Can MySQL Proxy currently accomplish this? My goal is to minimize connection latency while keeping temporary tables available.**

Yes.

**15.7.6.13: Are these reserved function names (for example, `error_result()`) that get automatically called?**

Only functions and values starting with `proxy.*` are provided by the proxy. All others are user provided.

**15.7.6.14: As the script is re-read by MySQL Proxy, does it cache this or is it looking at the file system with each request?**

It looks for the script at client-connect and reads it if it has changed, otherwise it uses the cached version.

**15.7.6.15: Given that there is a `connect_server()` function, can a Lua script link up with multiple servers?**

MySQL Proxy provides some tutorials in the source package; one is [examples/tutorial-keepalive.lua](#).

**15.7.6.16: Is the MySQL Proxy an API?**

No, MySQL Proxy is an application that forwards packets from a client to a server using the MySQL network protocol. The MySQL Proxy provides a API allowing you to change its behavior.

**15.7.6.17: The global namespace variable example with quotas does not persist after a reboot, is that correct?**

Yes. If you restart the proxy, you lose the results, unless you save them in a file.

**15.7.6.18: Can MySQL Proxy handle SSL connections?**

No, being the man-in-the-middle, Proxy cannot handle encrypted sessions because it cannot share the SSL information.

**15.7.6.19: Could MySQL Proxy be used to capture passwords?**

The MySQL network protocol does not allow passwords to be sent in cleartext, all you could capture is the encrypted version.

**15.7.6.20: Are there tools for isolating problems? How can someone figure out whether a problem is in the client, the database, or the proxy?**

You can set a debug script in the proxy, which is an exceptionally good tool for this purpose. You can see very clearly which component is causing the problem, if you set the right breakpoints.

**15.7.6.21: Is MySQL Proxy similar to what is provided by Java connection pools?**

Yes and no. Java connection pools are specific to Java applications, MySQL Proxy works with any client API that talks the MySQL network protocol. Also, connection pools do not provide any functionality for intelligently examining the network packets and modifying the contents.

**15.7.6.22: So authentication with connection pooling has to be done at every connection? What is the authentication latency?**

You can skip the round-trip and use the connection as it was added to the pool. As long as the application cleans up the temporary tables it used. The overhead is (as always) around 400 microseconds.

**15.7.6.23: If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?**

Yes, MySQL Proxy can listen on any port, provided that none of the MySQL servers are listening on the same port.

**15.7.6.24: What about caching the authorization information so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?**

There is an `--proxy-pool-no-change-user` option that provides this functionality.

**15.7.6.25: Is there any big web site using MySQL Proxy? For what purpose and what transaction rate have they achieved?**

Yes, [gaiaonline](#). They have tested MySQL Proxy and seen it handle 2400 queries per second through the proxy.

**15.7.6.26: How does MySQL Proxy compare to DBSlayer?**

DBSlayer is a REST->MySQL tool, MySQL Proxy is transparent to your application. No change to the application is needed.

**15.7.6.27: I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.**

This issue is fixed in version 0.7.0.

**15.7.6.28: Is it “safe” to use [LuaSocket](#) with proxy scripts?**

You can, but it is not advised because it may block.

**15.7.6.29: How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?**

Connection Pooling is just one use case of the MySQL Proxy. You can use it for a lot more and it works in cases where you cannot use DBCP (for example, if you do not have Java).

**15.7.6.30: MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?**

The server limit is given by the value of the [max\\_connections](#) system variable. The default value is version dependent.

**15.7.6.31: Would the Java-only connection pooling solution work for multiple web servers? With this, I would assume that you can pool across many web servers at once?**

Yes. But you can also start one proxy on each application server to get a similar behavior as you have it already.

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous by default - slaves need not to be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see [Section B.13, “MySQL 5.5 FAQ: Replication”](#).

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see [Chapter 16, MySQL Cluster NDB 7.2](#)). In MySQL 5.5, an interface to semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transac-

tion. See [Section 15.3.8, “Semisynchronous Replication”](#)

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 15.1.1, “How to Set Up Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 15.1.2, “Replication Formats”](#). In MySQL 5.5, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 15.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see [Section 15.4, “Replication Notes and Tips”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see [Section 15.2, “Replication Implementation”](#).

## 15.1. Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's `master.info` file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, [Section 15.1.1, “How to Set Up Replication”](#), deals with the configuration of the systems and provides methods for copying data between the master and slaves.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 15.1.2, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that

you may want to execute, see [Section 15.1.4, “Common Replication Administration Tasks”](#).

### 15.1.1. How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See [Section 15.1.1.1, “Setting the Replication Master Configuration”](#).
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Section 15.1.1.2, “Setting the Replication Slave Configuration”](#).
- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See [Section 15.1.1.3, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 15.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see [Section 15.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#)) or by copying the data files directly (see [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#)).
- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Section 15.1.1.10, “Setting the Master Configuration on the Slave”](#).

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see [Section 15.1.1.7, “Setting Up Replication with New Master and Slaves”](#).
- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see [Section 15.1.1.8, “Setting Up Replication with Existing Data”](#).
- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See [Section 15.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”](#).

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in [Section 12.4.1, “SQL Statements for Controlling Master Servers”](#), and [Section 12.4.2, “SQL Statements for Controlling Slave Servers”](#). You should also familiarize yourself with the replication startup options described in [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).

#### Note

Note that certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

#### 15.1.1.1. Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging *must* be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves.

If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and  $(2^{32})-1$ . How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

#### Note

If you omit `server-id` (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

#### Note

For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

#### Note

Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, your slave will not be able to communicate with the master and replication will fail.

### 15.1.1.2. Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

#### Note

If you omit `server-id` (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

### 15.1.1.3. Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file (see [Section 15.2.2.2, “Slave Status Logs”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement.

If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%mydomain.com';
```

See [Section 12.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

#### 15.1.1.4. Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For `InnoDB` tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

#### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.000003 | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ( `' '` ) and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be to synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to [Section 15.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#), or [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#). The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

#### 15.1.1.5. Creating a Data Snapshot Using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool. Once the data dump has been

completed, you then import this data into the slave before starting the replication process.

To obtain a snapshot of the data using `mysqldump`:

1. If you have not already locked the tables on the server to prevent statements that update data from executing:

Start a session on the server by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

Remember to use `SHOW MASTER STATUS` and record the binary log details for use when starting up the slave. The point in time of your snapshot and the binary log position must match. See [Section 15.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).

2. In another session, use `mysqldump` to create a dump either of all the databases you want to replicate, or of selected individual databases. For example:

```
shell> mysqldump --all-databases --lock-all-tables >dbdump.db
```

An alternative to using a bare dump, is to use the `--master-data` option, which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process.

```
shell> mysqldump --all-databases --master-data >dbdump.db
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Alternatively, exit the first session to release the read lock.

When choosing databases to include in the dump, remember to filter out databases on each slave that you do not want to include in the replication process.

Either to copy the dump file to the slave, or use the file from the master when connecting remotely to the slave to import the data.

### 15.1.1.6. Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using `mysqldump` and importing the file on each slave. This technique skips the overhead of updating indexes as the `INSERT` statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Chapter 24, MySQL Enterprise Backup](#) for detailed information.

Otherwise, use the `cold backup` technique to obtain a reliable binary snapshot of `InnoDB` tables: copy all data files after doing a `slow shutdown` of the MySQL Server.

To create a raw data snapshot of `MyISAM` tables, you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For `InnoDB`, all tables in all databases are stored in the `system tablespace` files, unless you have the `innodb_file_per_table` option enabled.)

You might want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The `master.info` file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 15.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 15.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

### 15.1.1.7. Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See [Section 15.1.1.1, “Setting the Replication Master Configuration”](#).
2. Start up the MySQL master.
3. Set up a user. See [Section 15.1.1.3, “Creating a User for Replication”](#).

4. Obtain the master status information. See [Section 15.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See [Section 15.1.1.2, “Setting the Replication Slave Configuration”](#).
7. Start up the MySQL slave.
8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Section 15.1.1.10, “Setting the Master Configuration on the Slave”](#).

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

### 15.1.1.8. Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See [Section 15.1.1.3, “Creating a User for Replication”](#).
2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See [Section 15.1.1.1, “Setting the Replication Master Configuration”](#).

If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see [Section 15.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#)) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

3. If your master server is already correctly configured, obtain its status (see [Section 15.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#)) and then use `mysqldump` to take a snapshot (see [Section 15.1.1.5, “Creating a Data Snapshot Using mysqldump”](#)) or take a raw snapshot of the live server using the guide in [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).
4. Update the configuration of the slave. See [Section 15.1.1.2, “Setting the Replication Slave Configuration”](#).
5. The next step depends on how you created the snapshot of data on the master.

If you used `mysqldump`:

- a. Start the slave, using the `--skip-slave-start` option so that replication does not start.
- b. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

- a. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

- b. Start the slave, using the `--skip-slave-start` option so that replication does not start.
6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Section 15.1.1.10, “Setting the Master Configuration on the Slave”](#).
7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

### Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

## 15.1.1.9. Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] FAILED TO OPEN THE RELAY LOG './OLD_SLAVE_HOSTNAME-RELAY-BIN.003525'
(RELAY_LOG_POS 22940879)
071118 16:44:10 [ERROR] COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION
```

```
071118 16:44:10 [ERROR] FAILED TO INITIALIZE THE MASTER INFO STRUCTURE
```

This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 15.1.3](#), “Replication and Binary Logging Options and Variables”, for more information about these options.)

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively—if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.  
If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
- b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
- c. Proceed with the remaining steps in this section.
3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.
4. Start the existing slave.
5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.
6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

### 15.1.1.10. Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_host_name',
-> MASTER_USER='replication_user_name',
-> MASTER_PASSWORD='replication_password',
-> MASTER_LOG_FILE='recorded_log_file_name',
-> MASTER_LOG_POS=recorded_log_position;
```

#### Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 12.4.2.1](#), “`CHANGE MASTER TO` Syntax”.

## 15.1.2. Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard statement-based binary logging format. In older versions of MySQL (5.1.4 and earlier), binary logging and replication used this format exclusively.

- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as *row-based replication* (often abbreviated as *RBR*). In row-based replication, the master writes *events* to the binary log that indicate how individual table rows are changed.
- The server can change the binary logging format in real time according to the type of event using *mixed-format logging*.

When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

In MySQL 5.5, statement-based format is the default.

**MySQL Cluster.** The default binary logging format in all MySQL Cluster NDB 6.x and 7.x releases is [ROW](#). MySQL Cluster Replication always uses row-based replication, and the [NDBCLUSTER](#) storage engine is incompatible with statement-based replication. Using [NDBCLUSTER](#) sets row-based logging format automatically. See [Section 16.6.2, “General Requirements for MySQL Cluster Replication”](#), for more information.

When using [MIXED](#) format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the [binlog\\_format](#) server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see [Section 12.7.4, “SET Syntax”](#).

You must have the [SUPER](#) privilege to set either the global or session [binlog\\_format](#) value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 15.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 18.7, “Binary Logging of Stored Programs”](#).

### 15.1.2.1. Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

#### Advantages of statement-based replication

- Proven technology that has existed in MySQL since 3.23.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

#### Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.** Not all statements which modify data (such as `INSERT`, `DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 15.4.1.8, “Replication of Invoked Features”](#), for more information.
  - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See [Section 15.4.1.12, “Replication and LIMIT”](#).
  - Statements using any of the following functions cannot be replicated properly using statement-based replication:
    - `LOAD_FILE()`
    - `UUID()`, `UUID_SHORT()`
    - `USER()`
    - `FOUND_ROWS()`
    - `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)
    - `GET_LOCK()`
    - `IS_FREE_LOCK()`
    - `IS_USED_LOCK()`
    - `MASTER_POS_WAIT()`
    - `RELEASE_LOCK()`
    - `SLEEP()`
    - `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `RAND()`, `NOW()`, and so forth.

For more information, see [Section 15.4.1.11, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
090213 16:58:54 [Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For InnoDB: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 15.4.1.24, “Slave Errors During Replication”](#).
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.

- Table definitions must be (nearly) identical on master and slave. See [Section 15.4.1.6, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

## Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

The `mysql` database is not replicated. The `mysql` database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`
  - `INSERT` statements with `AUTO_INCREMENT`
  - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

## Disadvantages of row-based replication

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

### 15.1.2.2. Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see [Section 15.1.2, “Replication Formats”](#), and [Section 15.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see [Section 16.6.3, “Known Issues in MySQL Cluster Replication”](#).

- **RBL, RBR, and temporary tables.** As noted in [Section 15.4.1.19, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format. When mixed format is in effect, “safe” statements involving temporary tables are logged using statement-based format. For more information, see [Section 15.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

#### Note

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave's copy of the table.)
- **Latency and binary log size.** Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 12.7.6.1, “BINLOG Syntax”](#)). This statement displays an event in printable form, but as a base 64-encoded string the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 5.1.3, “Server System Variables”](#).

#### Note

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value (see [Section 16.6, “MySQL Cluster Replication”](#)).

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

- **Lack of binary log checksums.** RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also [Section 12.4.2.1, “CHANGE MASTER TO Syntax”](#), for general information about setting up MySQL with SSL.
- **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements, a simple example of such a clause being `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` system variable for statement filtering, you must also use `--binlog_format=STATEMENT`.

In MySQL 5.5, you can do filtering based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with the statement-based and row-based logging formats.

- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact that your choice of replication format has on how they operate, see [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).

### 15.1.2.3. Determination of Safe and Unsafe Statements in Binary Logging

When speaking of the “safeness” of a statement in MySQL Replication, we are referring to whether a statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered safe (see [Section 15.4.1.9, “Replication and Floating-Point Values”](#)).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- No distinction is made in the treatment of safe and unsafe statements when the binary logging mode is `ROW`.
- If the binary logging format is `MIXED`, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- If the binary logging format is `STATEMENT`, statements flagged as being unsafe generate a warning to this effect. (Safe statements are logged normally.)

For more information, see [Section 15.1.2, “Replication Formats”](#).

**Statements considered unsafe.** Statements having the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.** These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

**Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and `LAST_INSERT_ID()`

For more information, see [Section 15.4.1.11, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. For exceptions, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

See [Section 15.4.1.33, “Replication and Variables”](#).

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.
- **Updates a table having an `AUTO_INCREMENT` column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

For more information, see [Section 15.4.1.1, “Replication and `AUTO\_INCREMENT`”](#).

- **`INSERT DELAYED` statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.
- **Updates using `LIMIT`.** The order in which rows are retrieved is not specified.

See [Section 15.4.1.12, “Replication and `LIMIT`”](#).

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 15.4.1.29, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

- **LOAD DATA INFILE statements.** Beginning with MySQL 5.5.6, `LOAD DATA INFILE` is considered unsafe, it causes a warning in statement-based mode, and a switch to row-based format when using mixed-format logging. See [Section 15.4.1.13, “Replication and LOAD DATA INFILE”](#).

For additional information, see [Section 15.4.1, “Replication Features and Issues”](#).

### 15.1.3. Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

<b>Command-Line Format</b>	<code>--server-id=#</code>
<b>Option-File Format</b>	<code>server-id</code>
<b>Option Sets Variable</b>	Yes, <code>server_id</code>
<b>Variable Name</b>	<code>server_id</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0 .. 4294967295</code>

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 15.1.3.2, “Replication Master Options and Variables”](#), and [Section 15.1.3.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id`, the default ID is 0, in which case a master refuses connections from all slaves, and a slave refuses to connect to a master. For more information, see [Section 15.1.1.2, “Setting the Replication Slave Configuration”](#).

#### 15.1.3.1. Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 15.1. Replication Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">abort-slave-event-count</a>	Yes	Yes				
<a href="#">Com_change_master</a>				Yes	Both	No
<a href="#">Com_show_master_status</a>				Yes	Both	No
<a href="#">Com_show_new_master</a>				Yes	Both	No
<a href="#">Com_show_slave_hosts</a>				Yes	Both	No
<a href="#">Com_show_slave_status</a>				Yes	Both	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
us						
Com_slave_start				Yes	Both	No
Com_slave_stop				Yes	Both	No
disconnect-slave-event-count	Yes	Yes				
init_slave	Yes	Yes	Yes		Global	Yes
log-slave-updates	Yes	Yes			Global	No
- Variable: log_slave_updates			Yes		Global	No
master-connect-retry	Yes	Yes				
master-host	Yes	Yes				
master-info-file	Yes	Yes

Section 15.1.3.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.2.4, “The Binary Log”.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

### 15.1.3.2. Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the [server-id](#) option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other replication master or slave. Example: [server-id=3](#).

For options used on the master for controlling binary logging, see Section 15.1.3.4, “Binary Log Options and Variables”.

- [auto\\_increment\\_increment](#)

<b>Command-Line Format</b>	<code>--auto-increment-increment[=#]</code>
<b>Option-File Format</b>	<code>auto_increment_increment</code>
<b>Option Sets Variable</b>	Yes, <a href="#">auto_increment_increment</a>
<b>Variable Name</b>	<a href="#">auto_increment_increment</a>
<b>Variable Scope</b>	Global, Session

<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1
	<b>Range</b>	1 .. 65535

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

### Note

`auto_increment_increment` is supported for use with NDB tables only.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
+-----+-----+
```

```

+-----+-----+
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)

```

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)

```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 15.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `auto_increment_offset`

<b>Command-Line Format</b>	<code>--auto-increment-offset[=#]</code>	
<b>Option-File Format</b>	<code>auto_increment_offset</code>	
<b>Option Sets Variable</b>	Yes, <code>auto_increment_offset</code>	
<b>Variable Name</b>	<code>auto_increment_offset</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>
	<b>Range</b>	<code>1 .. 65535</code>

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment`.

#### Note

`auto_increment_offset` is supported for use with `NDB` tables only.

### 15.1.3.3. Replication Slave Options and Variables

This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

**Startup options for replication slaves.** The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `-replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--abort-slave-event-count`

<b>Command-Line Format</b>	<code>--abort-slave-event-count=#</code>
<b>Option-File Format</b>	<code>abort-slave-event-count</code>

	Permitted Values	
	Type	numeric
	Default	0
	Min Value	0

When this option is set to some positive integer *value* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *value* log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays *Yes* in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

Command-Line Format	<code>--disconnect-slave-event-count=#</code>	
Option-File Format	<code>disconnect-slave-event-count</code>	
	Permitted Values	
	Type	numeric
	Default	0

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--log-slave-updates`

Command-Line Format	<code>--log-slave-updates</code>	
Option-File Format	<code>log-slave-updates</code>	
Option Sets Variable	Yes, <code>log_slave_updates</code>	
Variable Name	<code>log_slave_updates</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	boolean
	Default	<code>FALSE</code>

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. Prior to MySQL 5.5, the server would not start when using the `--log-slave-updates` option without also starting the server with the `--log-bin` option, and would fail with an error; in MySQL 5.5, only a warning is generated. (Bug #44663) `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, **A** serves as the master for the slave **B**, and **B** serves as the master for the slave **C**. For this to work, **B** must be both a master *and* a slave. You must start both **A** and **B** with `--log-bin` to enable binary logging, and **B** with the `--log-slave-updates` option so that updates received from **A** are logged by **B** to its binary log.

- `--log-slow-slave-statements`

Command-Line Format	<code>--log-slow-slave-statements</code>
---------------------	--

<b>Option-File Format</b>	<code>log-slow-slave-statements</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>off</code>

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

- `--log-warnings[=level]`

<b>Command-Line Format</b>	<code>--log-warnings[=#]</code>	
	<code>-W [#]</code>	
<b>Option-File Format</b>	<code>log-warnings</code>	
<b>Option Sets Variable</b>	Yes, <code>log_warnings</code>	
<b>Variable Name</b>	<code>log_warnings</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
<b>Disabled by</b>	<code>skip-log-warnings</code>	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>64</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>
	<b>Range</b>	<code>0 .. 18446744073709547520</code>

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section C.5.2.11, “Communication Errors and Aborted Connections”](#).

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-info-file=file_name`

<b>Command-Line Format</b>	<code>--master-info-file=file_name</code>	
<b>Option-File Format</b>	<code>master-info-file=file_name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>master.info</code>

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see [Section 15.2.2.2, “Slave Status Logs”](#).

- `--master-retry-count=count`

<b>Command-Line Format</b>	<code>--master-retry-count=#</code>	
<b>Option-File Format</b>	<code>master-retry-count</code>	
<b>Deprecated</b>	5.6.1	

	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	86400
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	86400
	Range	0 .. 18446744073709551615

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

- `--max-relay-log-size=size`

The size at which the server rotates relay log files automatically. For more information, see [Section 15.2.2, “Replication Relay and Status Logs”](#). The default size is 1GB.

- `--read-only`

Cause the slave to permit no updates except from slave threads or from users having the `SUPER` privilege. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

Command-Line Format	<code>--relay-log=name</code>	
Option-File Format	<code>relay-log</code>	
	Permitted Values	
	Type	file name

The basename for the relay log. The default basename is `host_name-relay-bin`. The server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the basename.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay log index file. You can override this behavior by specifying a different relay log index file basename using the `--relay-log-index` option.

Starting with MySQL 5.5.20, when the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Prior to MySQL 5.5.20, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.
- `--relay-log-index=file_name`

<b>Command-Line Format</b>	<code>--relay-log-index=name</code>	
<b>Option-File Format</b>	<code>relay-log-index</code>	
<b>Option Sets Variable</b>	Yes, <code>relay_log_index</code>	
<b>Variable Name</b>	<code>relay-log-index</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay logs. You can override this behavior by specifying a different relay log file basename using the `--relay-log` option.

- `--relay-log-info-file=file_name`

<b>Command-Line Format</b>	<code>--relay-log-info-file=file_name</code>	
<b>Option-File Format</b>	<code>relay-log-info-file</code>	
<b>Option Sets Variable</b>	Yes, <code>relay_log_info_file</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>relay-log.info</code>

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see [Section 15.2.2.2, “Slave Status Logs”](#).

- `--relay-log-purge={0|1}`

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-recovery={0|1}`

Enables automatic relay log recovery immediately following server startup, which means that the replication slave discards all unprocessed relay logs and retrieves them from the replication master. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

- `--relay-log-space-limit=size`

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the

master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

Command-Line Format	<code>--replicate-do-db=name</code>	
Option-File Format	<code>replicate-do-db</code>	
	Permitted Values	
	Type	string

The effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication,

only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

### Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

<b>Command-Line Format</b>	<code>--replicate-ignore-db=name</code>	
<b>Option-File Format</b>	<code>replicate-ignore-db</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

As with `--replicate-do-db`, the effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

### Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the

logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

<b>Command-Line Format</b>	<code>--replicate-do-table=name</code>	
<b>Option-File Format</b>	<code>replicate-do-table</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

<b>Command-Line Format</b>	<code>--replicate-ignore-table=name</code>	
<b>Option-File Format</b>	<code>replicate-ignore-table</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

<b>Command-Line Format</b>	<code>--replicate-rewrite-db=old_name-&gt;new_name</code>	
<b>Option-File Format</b>	<code>replicate-rewrite-db</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. This does not work for cross-database updates. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

If you use this option on the command line and the “>” character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

<b>Command-Line Format</b>	<code>--replicate-same-server-id</code>	
<b>Option-File Format</b>	<code>replicate-same-server-id</code>	

	Permitted Values	
	Type	boolean
	Default	FALSE

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-wild-do-table=name</code>	
Option-File Format	<code>replicate-wild-do-table</code>	
	Permitted Values	
	Type	string

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the “%” and “\_” wildcard characters, which have the same meaning as for the [LIKE](#) pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the “\_” and “%” characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-wild-ignore-table=name</code>	
Option-File Format	<code>replicate-wild-ignore-table</code>	
	Permitted Values	
	Type	string

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

<b>Command-Line Format</b>	<code>--report-host=host_name</code>	
<b>Option-File Format</b>	<code>report-host</code>	
<b>Option Sets Variable</b>	Yes, <code>report_host</code>	
<b>Variable Name</b>	<code>report-host</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

<b>Command-Line Format</b>	<code>--report-password=name</code>	
<b>Option-File Format</b>	<code>report-password</code>	
<b>Option Sets Variable</b>	Yes, <code>report_password</code>	
<b>Variable Name</b>	<code>report-password</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

<b>Command-Line Format</b>	<code>--report-port=#</code>	
<b>Option-File Format</b>	<code>report-port</code>	
<b>Option Sets Variable</b>	Yes, <code>report_port</code>	
<b>Variable Name</b>	<code>report-port</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>3306</code>

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-user=user_name`

<b>Command-Line Format</b>	<code>--report-user=name</code>
----------------------------	---------------------------------

<b>Option-File Format</b>	<code>report-user</code>	
<b>Option Sets Variable</b>	Yes, <code>report_user</code>	
<b>Variable Name</b>	<code>report-user</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info`

<b>Command-Line Format</b>	<code>--show-slave-auth-info</code>	
<b>Option-File Format</b>	<code>show-slave-auth-info</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

<b>Command-Line Format</b>	<code>--skip-slave-start</code>	
<b>Option-File Format</b>	<code>skip-slave-start</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

<b>Command-Line Format</b>	<code>--slave_compressed_protocol</code>	
<b>Option-File Format</b>	<code>slave_compressed_protocol</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_compressed_protocol</code>	
<b>Variable Name</b>	<code>slave_compressed_protocol</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=file_name`

<b>Command-Line Format</b>	<code>--slave-load-tmpdir=path</code>	
<b>Option-File Format</b>	<code>slave-load-tmpdir</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_load_tmpdir</code>	
<b>Variable Name</b>	<code>slave_load_tmpdir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>/tmp</code>

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

<b>Command-Line Format</b>	<code>--slave-net-timeout=#</code>	
<b>Option-File Format</b>	<code>slave-net-timeout</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_net_timeout</code>	
<b>Variable Name</b>	<code>slave_net_timeout</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>3600</code>
	<b>Min Value</b>	<code>1</code>

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MAS-TER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix C, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

**Obsolete options.** *The following options are removed in MySQL 5.5. If you attempt to start `mysqld` with any of these options in MySQL 5.5, the server aborts with an `UNKNOWN VARIABLE` error.* To set the replication parameters formerly associated with these options, you must use the `CHANGE MASTER TO ...` statement (see [Section 12.4.2.1, “CHANGE MASTER TO Syntax”](#)).

The options affected are shown in this list:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

**System variables used on replication slaves.** The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

<b>Command-Line Format</b>	<code>--init-slave=name</code>	
<b>Option-File Format</b>	<code>init_slave</code>	
<b>Option Sets Variable</b>	Yes, <code>init_slave</code>	
<b>Variable Name</b>	<code>init_slave</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

#### **Note**

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 12.4.2.5, “START SLAVE Syntax”](#), for more information.

- `relay_log_index`

<b>Command-Line Format</b>	<code>--relay-log-index</code>	
<b>Option-File Format</b>	<code>relay_log_index</code>	
<b>Option Sets Variable</b>	Yes, <code>relay_log_index</code>	
<b>Variable Name</b>	<code>relay_log_index</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>*host_name*-relay-bin.index</code>

The name of the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

<b>Command-Line Format</b>	<code>--relay-log-info-file=file_name</code>	
<b>Option-File Format</b>	<code>relay_log_info_file</code>	
<b>Option Sets Variable</b>	Yes, <code>relay_log_info_file</code>	
<b>Variable Name</b>	<code>relay_log_info_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>relay-log.info</code>

The name of the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `relay_log_recovery`

<b>Command-Line Format</b>	<code>--relay-log-recovery</code>	
<b>Option-File Format</b>	<code>relay_log_recovery</code>	
<b>Option Sets Variable</b>	Yes, <code>relay_log_recovery</code>	
<b>Variable Name</b>	<code>relay_log_recovery</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Enables automatic relay log recovery immediately following server startup, which means that the replication slave discards all unprocessed relay logs and retrieves them from the replication master. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled). This global variable can be changed dy-

namically, or by starting the slave with the `--relay-log-recovery` option.

- `rpl_recovery_rank`

This variable is unused, and is removed in MySQL 5.6.

- `slave_compressed_protocol`

<b>Command-Line Format</b>	<code>--slave_compressed_protocol</code>	
<b>Option-File Format</b>	<code>slave_compressed_protocol</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_compressed_protocol</code>	
<b>Variable Name</b>	<code>slave_compressed_protocol</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_exec_mode`

<b>Variable Name</b>	<code>slave_exec_mode</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>STRICT (ALL)</code>
	<b>Default</b>	<code>IDEMPOTENT (NDB)</code>
	<b>Valid Values</b>	<code>IDEMPOTENT</code> <code>STRICT</code>

Controls whether `IDEMPOTENT` or `STRICT` mode is used in replication conflict resolution and error checking. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. This mode should be employed in multi-master replication, circular replication, and some other special replication scenarios. `STRICT` mode is the default, and is suitable for most other cases.

### Note

MySQL Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as `IDEMPOTENT`.

- `slave_load_tmpdir`

<b>Command-Line Format</b>	<code>--slave-load-tmpdir=path</code>
<b>Option-File Format</b>	<code>slave-load-tmpdir</code>
<b>Option Sets Variable</b>	Yes, <code>slave_load_tmpdir</code>
<b>Variable Name</b>	<code>slave_load_tmpdir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

	<b>Permitted Values</b>	
	<b>Type</b>	file name
	<b>Default</b>	/tmp

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_net_timeout`

<b>Command-Line Format</b>	<code>--slave-net-timeout=#</code>	
<b>Option-File Format</b>	<code>slave-net-timeout</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_net_timeout</code>	
<b>Variable Name</b>	<code>slave_net_timeout</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	3600
	<b>Min Value</b>	1

The number of seconds to wait for more data from a master/slave connection before aborting the read.

- `slave_skip_errors`

<b>Command-Line Format</b>	<code>--slave-skip-errors=name</code>	
<b>Option-File Format</b>	<code>slave-skip-errors</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_skip_errors</code>	
<b>Variable Name</b>	<code>slave_skip_errors</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_transaction_retries`

<b>Command-Line Format</b>	<code>--slave_transaction_retries=#</code>	
<b>Option-File Format</b>	<code>slave_transaction_retries</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_transaction_retries</code>	
<b>Variable Name</b>	<code>slave_transaction_retries</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	

	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	0 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	0 .. 18446744073709547520

If a replication slave SQL thread fails to execute a transaction because of an [InnoDB](#) deadlock or because the transaction's execution time exceeded [InnoDB's innodb\\_lock\\_wait\\_timeout](#) or [NDBCLUSTER's TransactionDeadlockDetectionTimeout](#) or [TransactionInactiveTimeout](#), it automatically retries [slave\\_transaction\\_retries](#) times before stopping with an error. The default value is 10.

- [slave\\_type\\_conversions](#)

Version Introduced	5.5.3	
Command-Line Format	<code>--slave_type_conversions=set</code>	
Option-File Format	<code>slave_type_conversions</code>	
Option Sets Variable	Yes, <code>slave_type_conversions</code>	
Variable Name	<code>slave_type_conversions</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>set</code>
	Default	
	Valid Values	<code>ALL_LOSSY</code>
		<code>ALL_NON_LOSSY</code>
<code>ALL_LOSSY,ALL_NON_LOSSY</code>		

Controls the type conversion mode in effect on the slave when using row-based replication, including MySQL Cluster Replication. Its value is a comma-delimited set of zero or more elements from the list: [ALL\\_LOSSY](#), [ALL\\_NON\\_LOSSY](#). Set this variable to an empty string to disallow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

This variable was added in MySQL 5.5.3.

- [sql\\_slave\\_skip\\_counter](#)

<b>Variable Name</b>	<a href="#">sql_slave_skip_counter</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes

	Permitted Values	
Type	numeric	

The number of events from the master that a slave server should skip.

### Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 12.4.2.4, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

- `sync_master_info`

Command-Line Format	<code>--sync-master-info=#</code>	
Option-File Format	<code>sync_master_info</code>	
Option Sets Variable	Yes, <code>sync_master_info</code>	
Variable Name	<code>sync_master_info</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	0
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	0
	Range	0 .. 18446744073709547520

If the value of this variable is greater than 0, a replication slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. The default value of `sync_relay_log_info` is 0 (recommended in most situations), which does not force any synchronization to disk by the MySQL server; in this case, the server relies on the operating system to flush the `master.info` file's contents from time to time as for any other file.

- `sync_relay_log`

Command-Line Format	<code>--sync-relay-log=#</code>	
Option-File Format	<code>sync_relay_log</code>	
Option Sets Variable	Yes, <code>sync_relay_log</code>	
Variable Name	<code>sync_relay_log</code>	
Variable Scope	Global	
Dynamic Variable	Yes	

	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 18446744073709547520

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatsync()`) after every `sync_relay_log` writes to the relay log. There is one write to the relay log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_relay_log` is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

<b>Command-Line Format</b>	<code>--sync-relay-log-info=#</code>	
<b>Option-File Format</b>	<code>sync_relay_log_info</code>	
<b>Option Sets Variable</b>	Yes, <code>sync_relay_log_info</code>	
<b>Variable Name</b>	<code>sync_relay_log_info</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 18446744073709547520

If the value of this variable is greater than 0, a replication slave synchronizes its `relay-log.info` file to disk (using `fdatsync()`) after every `sync_relay_log_info` transactions. A value of 1 is the generally the best choice. The default value of `sync_relay_log_info` is 0, which does not force any synchronization to disk by the MySQL server—in this case, the server relies on the operating system to flush the `relay-log.info` file's contents from time to time as for any other file.

#### 15.1.3.4. Binary Log Options and Variables

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well

as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.2.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.2, “Server Command Options”](#), and [Section 5.1.3, “Server System Variables”](#).

**Startup options used with binary logging.** The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

<b>Command-Line Format</b>	<code>--binlog-row-event-max-size=#</code>	
<b>Option-File Format</b>	<code>binlog-row-event-max-size</code>	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	1024
	<b>Range</b>	256 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	1024
	<b>Range</b>	256 .. 18446744073709547520

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See [Section 15.1.2, “Replication Formats”](#).

- `--log-bin[=base_name]`

<b>Command-Line Format</b>	<code>--log-bin</code>	
<b>Option-File Format</b>	<code>log-bin</code>	
<b>Variable Name</b>	<code>log_bin</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name
	<b>Default</b>	OFF

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 5.2.4, “The Binary Log”](#).

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see [Section C.5.8, “Known Issues in MySQL”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the basename.

In MySQL 5.5.20 and later, when the server reads an entry from the index file, it checks whether the entry contains a relative path, and if it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previous to MySQL 5.5.20, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the basename. This is a known issue; see Bug #19614 for more information.

- `--log-bin-index[=file_name]`

<b>Command-Line Format</b>	<code>--log-bin-index=name</code>	
<b>Option-File Format</b>	<code>log-bin-index</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>OFF</code>

The index file for binary log file names. See [Section 5.2.4, “The Binary Log”](#). If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

<b>Version Removed</b>	5.5.3	
<b>Command-Line Format</b>	<code>--log-bin-trust-function-creators</code>	
<b>Option-File Format</b>	<code>log-bin-trust-function-creators</code>	
<b>Option Sets Variable</b>	Yes, <code>log_bin_trust_function_creators</code>	
<b>Variable Name</b>	<code>log_bin_trust_function_creators</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 18.7, “Binary Logging of Stored Programs”](#).

- `--log-bin-use-v1-row-events[={0|1}]`

<b>Version Introduced</b>	5.5.15-ndb-7.2.1	
<b>Command-Line Format</b>	<code>--log-bin-use-v1-row-events[={0 1}]</code>	
<b>Option-File Format</b>	<code>log-bin-use-v1-row-events</code>	
<b>Option Sets Variable</b>	Yes, <code>log_bin_use_v1_row_events</code>	
<b>Variable Name</b>	<code>log-bin-use-v1-row-events</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>1</code>
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>1</code>
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>0</code>

Version 2 binary log row events are used by default beginning with MySQL Cluster NDB 7.2.1; however, Version 2 events cannot be read by previous MySQL Cluster releases. Setting `--log-bin-use-v1-row-events` to 1 causes `mysqld` to write the bin-

ary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

### Note

Version 2 binary log row events are also available in MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.6 and later MySQL Cluster NDB 7.0 and 7.1 releases. However, prior to MySQL Cluster NDB 7.2.1, Version 1 events are the default (and so the default value for this option is 1 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

`--log-bin-use-v1-row-events` is not supported in mainline MySQL Server 5.5 releases.

For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `--log-short-format`

<b>Command-Line Format</b>	<code>--log-short-format</code>	
<b>Option-File Format</b>	<code>log-short-format</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Log less information to the binary log and slow query log, if they have been activated.

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 15.1.3.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

<b>Command-Line Format</b>	<code>--binlog-do-db=name</code>	
<b>Option-File Format</b>	<code>binlog-do-db</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	string

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain com-

mas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

Command-Line Format	<code>--binlog-ignore-db=name</code>	
Option-File Format	<code>binlog-ignore-db</code>	
	Permitted Values	
	Type	<code>string</code>

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

<b>Command-Line Format</b>	<code>--max-binlog-dump-events=#</code>	
<b>Option-File Format</b>	<code>max-binlog-dump-events</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

<b>Command-Line Format</b>	<code>--sporadic-binlog-dump-fail</code>	
<b>Option-File Format</b>	<code>sporadic-binlog-dump-fail</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

This option is used internally by the MySQL test suite for replication testing and debugging.

**System variables used with the binary log.** The following list describes system variables for controlling binary logging. They can be

set at server startup and some of them can be changed at runtime using [SET](#). Server options used to control binary logging are listed earlier in this section.

- [binlog\\_cache\\_size](#)

<b>Command-Line Format</b>	<code>--binlog_cache_size=#</code>	
<b>Option-File Format</b>	<code>binlog_cache_size</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">binlog_cache_size</a>	
<b>Variable Name</b>	<a href="#">binlog_cache_size</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	32768
	<b>Range</b>	4096 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	32768
	<b>Range</b>	4096 .. 18446744073709547520

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The [Binlog\\_cache\\_use](#) and [Binlog\\_cache\\_disk\\_use](#) status variables can be useful for tuning the size of this variable. See [Section 5.2.4, “The Binary Log”](#).

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the size for both caches. This means that, in these MySQL versions, the total memory used for these caches is double the value set for [binlog\\_cache\\_size](#).

Beginning with MySQL 5.5.9, [binlog\\_cache\\_size](#) sets the size for the transaction cache only, and the size of the statement cache is governed by the [binlog\\_stmt\\_cache\\_size](#) system variable.

- [binlog\\_direct\\_non\\_transactional\\_updates](#)

<b>Version Introduced</b>	5.5.2	
<b>Command-Line Format</b>	<code>--binlog_direct_non_transactional_updates[=value]</code>	
<b>Option-File Format</b>	<code>binlog_direct_non_transactional_updates</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">binlog_direct_non_transactional_updates</a>	
<b>Variable Name</b>	<a href="#">binlog_direct_non_transactional_updates</a>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">boolean</a>
	<b>Default</b>	OFF

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and non-transactional tables. MySQL tries to preserve causality among these statements by writing non-transactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf

of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

Beginning with MySQL 5.5.2, the `binlog_direct_non_transactional_updates` variable offers one possible work-around to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

### Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

Beginning with MySQL 5.5.5, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- `binlog_format`

<b>Command-Line Format</b>	<code>--binlog-format=format</code>	
<b>Option-File Format</b>	<code>binlog-format=format</code>	
<b>Option Sets Variable</b>	Yes, <code>binlog_format</code>	
<b>Variable Name</b>	<code>binlog_format</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	<code>STATEMENT</code>
	<b>Valid Values</b>	<code>ROW</code>  <code>STATEMENT</code>  <code>MIXED</code>

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See [Section 15.1.2, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

### Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

In MySQL 5.5, the default format is `STATEMENT`.

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. See [Section 12.7.4, “SET Syntax”](#), for more information.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the `NDBCLUSTER` storage engine is enabled.
- If the session is currently in row-based replication mode and has open temporary tables.
- Beginning with MySQL 5.5.3, within a transaction. (Bug #47863)

Trying to switch the format in those cases results in an error.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `log_bin_use_v1_row_events`

<b>Version Introduced</b>	5.5.15-ndb-7.2.1	
<b>Command-Line Format</b>	<code>--log-bin-use-v1-row-events[={0 1}]</code>	
<b>Option-File Format</b>	<code>log_bin_use_v1_row_events</code>	
<b>Option Sets Variable</b>	Yes, <code>log_bin_use_v1_row_events</code>	
<b>Variable Name</b>	<code>log_bin_use_v1_row_events</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>1</code>
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>1</code>
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>0</code>

Shows whether Version 2 binary logging, available beginning with MySQL Cluster NDB 7.2.1, is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of MySQL Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

### Note

MySQL Cluster NDB 7.2.1 and later use Version 2 binary log row events by default (and so the default value for this vari-

able changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

This variable is not supported in mainline MySQL Server 5.5.

For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `max_binlog_cache_size`

<b>Command-Line Format</b>	<code>--max_binlog_cache_size=#</code>	
<b>Option-File Format</b>	<code>max_binlog_cache_size</code>	
<b>Option Sets Variable</b>	Yes, <code>max_binlog_cache_size</code>	
<b>Variable Name</b>	<code>max_binlog_cache_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>18446744073709547520</code>
	<b>Range</b>	<code>4096 .. 18446744073709547520</code>

If a transaction requires more than this many bytes of memory, the server generates a `MULTI-STATEMENT TRANSACTION REQUIRED MORE THAN 'MAX_BINLOG_CACHE_SIZE' BYTES OF STORAGE` error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16PB (petabytes) on 64-bit platforms.

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the upper limit for both caches. This means that, in these MySQL versions, the effective maximum for these caches is double the value set for `max_binlog_cache_size`.

Beginning with MySQL 5.5.9, `max_binlog_cache_size` sets the size for the transaction cache only, and the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

Also beginning with MySQL 5.5.9, the session visibility of the `max_binlog_cache_size` system variable matches that of the `binlog_cache_size` system variable: In MySQL 5.5.8 and earlier releases, a change in `max_binlog_cache_size` took immediate effect; in MySQL 5.5.9 and later, a change in `max_binlog_cache_size` takes effect only for new sessions that started after the value is changed.

- `max_binlog_stmt_cache_size`

<b>Version Introduced</b>	5.5.9	
<b>Command-Line Format</b>	<code>--max_binlog_stmt_cache_size=#</code>	
<b>Option-File Format</b>	<code>max_binlog_stmt_cache_size</code>	
<b>Option Sets Variable</b>	Yes, <code>max_binlog_stmt_cache_size</code>	
<b>Variable Name</b>	<code>max_binlog_stmt_cache_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>18446744073709547520</code>
	<b>Range</b>	<code>4096 .. 18446744073709547520</code>

If nontransaction statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16PB (petabytes) on 64-bit platforms.

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the upper limit for both caches. This means that, in these MySQL versions, the effective maximum for these caches is double the value set for `max_binlog_cache_size`.

Beginning with MySQL 5.5.9, `max_binlog_stmt_cache_size` sets the size for the transaction cache only, and the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `max_binlog_size`

<b>Command-Line Format</b>	<code>--max_binlog_size=#</code>	
<b>Option-File Format</b>	<code>max_binlog_size</code>	
<b>Option Sets Variable</b>	Yes, <code>max_binlog_size</code>	
<b>Variable Name</b>	<code>max_binlog_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1073741824</code>
	<b>Range</b>	<code>4096 .. 1073741824</code>

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `binlog_stmt_cache_size`

<b>Version Introduced</b>	5.5.9	
<b>Command-Line Format</b>	<code>--binlog_stmt_cache_size=#</code>	
<b>Option-File Format</b>	<code>binlog_stmt_cache_size</code>	
<b>Option Sets Variable</b>	Yes, <code>binlog_stmt_cache_size</code>	
<b>Variable Name</b>	<code>binlog_stmt_cache_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>32</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>32768</code>
	<b>Range</b>	<code>4096 .. 4294967295</code>
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>64</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>32768</code>
	<b>Range</b>	<code>4096 .. 18446744073709547520</code>

Beginning with MySQL 5.5.9, this variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. In MySQL 5.5.3 and later, separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large nontransactional statements during transactions, you can increase this cache size to get more performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.2.4, “The Binary Log”](#).

In MySQL 5.5.3 through 5.5.8, the size for both caches is set using `binlog_cache_size`. This means that, in these MySQL versions, the total memory used for these caches is double the value set for `binlog_cache_size`. Beginning with MySQL 5.5.9, `binlog_cache_size` sets the size for the transaction cache only.

- `sync_binlog`

<b>Command-Line Format</b>	<code>--sync-binlog=#</code>	
<b>Option-File Format</b>	<code>sync_binlog</code>	
<b>Option Sets Variable</b>	Yes, <code>sync_binlog</code>	
<b>Variable Name</b>	<code>sync_binlog</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 18446744073709547520

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

## 15.1.4. Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

### 15.1.4.1. Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: master1
      Master_User: root
      Master_Port: 3306
```

```

Connect_Retry: 60
Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
Relay_Log_File: slave1-relay-bin.000056
Relay_Log_Pos: 950
Relay_Master_Log_File: mysql-bin.000004
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Master_Log_Pos: 931
Relay_Log_Space: 1365
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
Last_IO_Errno: 0
Last_IO_Error:
Last_SQL_Errno: 0
Last_SQL_Error:
Replicate_Ignore_Server_Ids: 0

```

The key fields from the status report to examine are:

- **Slave\_IO\_State**: The current status of the slave. See [Section 7.12.5.6, “Replication Slave I/O Thread States”](#), and [Section 7.12.5.7, “Replication Slave SQL Thread States”](#), for more information.
- **Slave\_IO\_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP SLAVE**.
- **Slave\_SQL\_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.
- **Last\_IO\_Error**, **Last\_SQL\_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- **Seconds\_Behind\_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for **Seconds\_Behind\_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave\_net\_timeout** has not yet elapsed.

It is also possible that transient values for **Seconds\_Behind\_Master** may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, **Seconds\_Behind\_Master** displays 0; but when the slave I/O thread is still queuing up a new event, **Seconds\_Behind\_Master** may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute **SHOW SLAVE STATUS** several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (**Master\_Log\_file**, **Read\_Master\_Log\_Pos**): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (**Relay\_Master\_Log\_File**, **Exec\_Master\_Log\_Pos**): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.

- ([Relay\\_Log\\_File](#), [Relay\\_Log\\_Pos](#)): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using [SHOW PROCESSLIST](#) to examine the list of running processes. Slave connections have [Binlog Dump](#) in the [Command](#) field:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
   Id: 10
  User: root
 Host: slave1:58371
   db: NULL
Command: Binlog Dump
   Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the [--report-host](#) option and are connected to the master, the [SHOW SLAVE HOSTS](#) statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the [--report-host](#) option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
|         10 | slave1 | 3306 |                0 |          1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

#### 15.1.4.2. Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the [STOP SLAVE](#) and [START SLAVE](#) statements.

To stop processing of the binary log from the master, use [STOP SLAVE](#):

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the [START SLAVE](#) statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

## 15.2. Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 15.2.1, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 7.12.5, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 15.2.2, “Replication Relay and Status Logs”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 15.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

### 15.2.1. Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.  
  
The binlog dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.
- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.  
  
The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.  
  
The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.
- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binlog dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 7.12.5.5, “Replication Master Thread States”](#). For slave states, see [Section 7.12.5.6, “Replication Slave I/O Thread States”](#), and [Section 7.12.5.7, “Replication Slave SQL Thread States”](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread that services a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
  User: system user
  Host:
  db: NULL
Command: Connect
  Time: 11
  State: Waiting for master to send event
  Info: NULL
***** 2. row *****
  Id: 11
  User: system user
  Host:
  db: NULL
Command: Connect
  Time: 11
  State: Has read all relay log; waiting for the slave I/O
        thread to update it
  Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section B.13, “MySQL 5.5 FAQ: Replication”](#). If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 5.1.3, “Server System Variables”](#).

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See [Section 15.1.4.1, “Checking Replication Status”](#).

## 15.2.2. Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.
- The *relay log info log* holds status information about the execution point within the slave's relay log.

### 15.2.2.1. The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `FAILED TO OPEN THE RELAY LOG` and `COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION`. This is a known issue (see Bug #2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 15.2.2.2. Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. See [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 12.4.2, “SQL Statements for Controlling Slave Servers”](#). Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log should be protected because it contains the password for connecting to the master. See [Section 5.3.2.1, “Administrator Guidelines for Password Security”](#).

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file and the columns displayed by `SHOW SLAVE STATUS`.

Line in <code>master.info</code>	<code>SHOW SLAVE STATUS</code> Column	Description
1		Number of lines in the file
2	<code>Master_Log_File</code>	The name of the master binary log currently being read from the master
3	<code>Read_Master_Log_Pos</code>	The current position within the master binary log that have been read from the master
4	<code>Master_Host</code>	The host name of the master
5	<code>Master_User</code>	The user name used to connect to the master
6	Password (not shown by <code>SHOW SLAVE STATUS</code> )	The password used to connect to the master
7	<code>Master_Port</code>	The network port used to connect to the master
8	<code>Connect_Retry</code>	The period (in seconds) that the slave will wait before trying to re-connect to the master
9	<code>Master_SSL_Allowed</code>	Indicates whether the server supports SSL connections
10	<code>Master_SSL_CA_File</code>	The file used for the Certificate Authority (CA) certificate
11	<code>Master_SSL_CA_Path</code>	The path to the Certificate Authority (CA) certificates
12	<code>Master_SSL_Cert</code>	The name of the SSL certificate file
13	<code>Master_SSL_Cipher</code>	The list of possible ciphers used in the handshake for the SSL connection
14	<code>Master_SSL_Key</code>	The name of the SSL key file
15	<code>Master_SSL_Verify_Server_Cert</code>	Whether to verify the server certificate
17	<code>Replicate_Ignore_Server_Ids</code>	The number of server IDs to be ignored, followed by the actual server IDs

The slave SQL thread updates the relay log info log. The following table shows the correspondence between the lines in the `relay-log.info` file and the columns displayed by `SHOW SLAVE STATUS`.

Line in <code>relay-log.info</code>	<code>SHOW SLAVE STATUS</code> Column	Description
1	<code>Relay_Log_File</code>	The name of the current relay log file
2	<code>Relay_Log_Pos</code>	The current position within the relay log file; events up to this position have been executed on the slave database
3	<code>Relay_Master_Log_File</code>	The name of the master binary log file from which the events in the relay log file were read
4	<code>Exec_Master_Log_Pos</code>	The equivalent position within the master's binary log file of events that have already been executed

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

### 15.2.3. How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 15.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).)

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 15.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no matching database-level options are found, option checking proceeds to any table-level options that may be in use, as discussed in [Section 15.2.3.2, “Evaluation of Table-Level Replication Options”](#).

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options. An example of the latter that may have unintended effects is the use of `--replicate-do-db` and `--replicate-wild-do-table` together, where `--replicate-wild-do-table` uses a pattern for the database name that matches the name given for `--replicate-do-db`. Suppose a replication slave is started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. Then, suppose that on the master, you issue the statement `CREATE DATABASE dbx`. Although you might expect it, this statement is not replicated because it does not reference a table named `t1`.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

#### Note

In MySQL 5.5, database-level filtering options are case-sensitive on platforms supporting case sensitivity in filenames, whereas table-level filtering options are not (regardless of platform). This is true regardless of the value of the `lower_case_table_names` system variable.

### 15.2.3.1. Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
  - **Yes.** Do any of them match the database?
  - **Yes.** Execute the statement and exit.

- **No.** Continue to step 2.
  - **No.** Continue to step 2.
2. Are there any `--replicate-ignore-db` options?
    - **Yes.** Do any of them match the database?
      - **Yes.** Ignore the statement and exit.
      - **No.** Continue to step 3.
    - **No.** Continue to step 3.
  3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 15.2.3.2, “Evaluation of Table-Level Replication Options”](#).

### Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by [USE](#))?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

### Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

### 15.2.3.2. Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if no matching database options were found (see [Section 15.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

#### Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.

The following steps describe this evaluation in more detail:

1. Are there any table options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 5.
  - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 6.
  - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
  - **Yes.** Ignore the event and exit.
  - **No.** Execute the event and exit.

### 15.2.3.3. Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No <code>--replicate-*</code> options at all:	The slave executes all events that it receives from the master.
<code>--replicate-*-db</code> options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.

Condition (Types of Options)	Outcome
<code>--replicate-*-table</code> options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

## 15.3. Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 15.3.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 15.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 15.3.3, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 15.3.4, “Replicating Different Databases to Different Slaves”](#).

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as an replication master, see [Section 15.3.5, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 15.3.6, “Switching Masters During Failover”](#).

To secure your replication communication, you can use SSL to encrypt the communication channel. For step-by-step instructions, see [Section 15.3.7, “Setting Up Replication Using SSL”](#).

### 15.3.1. Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 15.3.1.1, “Backing Up a Slave Using `mysqldump`”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 15.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 15.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

### 15.3.1.1. Backing Up a Slave Using `mysqldump`

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 15.1.4.1, “Checking Replication Status”](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 15.3.4, “Replicating Different Databases to Different Slaves”](#).

### 15.3.1.2. Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place

while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as [InnoDB](#). With [InnoDB](#), these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including [cp](#), [tar](#) or [WinZip](#). For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, [master.info](#) and [relay-log.info](#), along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the [relay-log.info](#) file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use [CHANGE MASTER TO](#) with the [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating [LOAD DATA INFILE](#) statements, you should also back up any [SQL\\_LOAD-\\*](#) files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted [LOAD DATA INFILE](#) operations. The location of this directory is the value of the [--slave-load-tmpdir](#) option. If the server was not started with that option, the directory location is the value of the [tmpdir](#) system variable.

### 15.3.1.3. Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the [read\\_only](#) system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

#### Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as [mysqldump](#) (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

### Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

### Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

## 15.3.2. Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 15.3.3, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the `InnoDB` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `default_storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

### 15.3.3. Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 15.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 15.1. Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`

- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 15.3.4. Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 15.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#).

**Figure 15.2. Using Replication to Replicate Databases to Separate Replication Slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

#### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 15.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.

- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

**Note**

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

### 15.3.5. Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 15.3, “Using an Additional Replication Host to Improve Performance”](#).

**Figure 15.3. Using an Additional Replication Host to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 15.3.4, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 15.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

### 15.3.6. Switching Masters During Failover

There is currently no official solution for providing failover between master and slaves in the event of a failure. With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start reading and executing events from the specified binary log coordinates on the new master. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE; RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in [Figure 15.4, “Redundancy Using Replication, Initial Structure”](#).

**Figure 15.4. Redundancy Using Replication, Initial Structure**

In this diagram, the **MySQL Master** holds the master database, the **MySQL Slave** hosts are replication slaves, and the **Web Client** machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 15.3.3, “Using Replication for Scale-Out”](#).

Each **MySQL Slave** (**Slave 1**, **Slave 2**, and **Slave 3**) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason **MySQL Master** becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick **Slave 1**, all **Web Clients** should be redirected to **Slave 1**, which will log updates to its binary log. **Slave 2** and **Slave 3** should then replicate from **Slave 1**.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that **Slave 1** has `--log-slave-updates` enabled. Then it will write updates that it receives from **Master** to its own binary log. When **Slave 2** changes from **Master** to **Slave 1** as its master, it may receive updates from **Slave 1** that it has already received from **Master**.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave **Slave 1** being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves **Slave 2** and **Slave 3**, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of **Slave 1**). To use `CHANGE MASTER TO`, add all information about how to connect to **Slave 1** from **Slave 2** or **Slave 3** (`user,password,port`). In `CHANGE MASTER TO`, there is no need to specify the name of the **Slave 1** binary log file or log position to read from: We know it is the first binary log file and position 4, which are the defaults for `CHANGE MASTER TO`. Finally, use `START SLAVE` on **Slave 2** and **Slave 3**.

Once the new replication is in place, you will then need to instruct each **Web Client** to direct its statements to **Slave 1**. From that point on, all updates statements sent by **Web Client** to **Slave 1** are written to the binary log of **Slave 1**, which then contains

every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 15.5, “Redundancy Using Replication, After Master Failure”.

**Figure 15.5. Redundancy Using Replication, After Master Failure**

When `Master` is up again, you must issue on it the same `CHANGE MASTER TO` as that issued on `Slave 2` and `Slave 3`, so that `Master` becomes a slave of `S1` and picks up each `Web Client` writes that it missed while it was down.

To make `Master` a master again (for example, because it is the most powerful machine), use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. Otherwise, they may pick up old `Web Client` writes from before the point at which `Master` became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.

### 15.3.7. Setting Up Replication Using SSL

To use SSL for encrypting the transfer of the binary log required during replication, both the master and the slave must support SSL network connections. If either host does not support SSL connections (because it has not been compiled or configured for SSL), replication through an SSL connection is not possible.

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

For more information on setting up a server and client for SSL connectivity, see [Section 5.5.8.2, “Using SSL Connections”](#).

To enable SSL on the master you must create or obtain suitable certificates, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the certificates may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slave certificates to the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement:

- To add the slave certificates using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to enable SSL connectivity:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1;
```

- To specify the SSL certificate options using the `CHANGE MASTER TO` statement, append the SSL options:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1,
-> MASTER_SSL_CA = 'ca_file_name',
-> MASTER_SSL_CAPATH = 'ca_directory_name',
-> MASTER_SSL_CERT = 'cert_file_name',
-> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that the SSL connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see [Section 12.4.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce the use of SSL connections during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> GRANT USAGE ON *.*
-> TO 'repl'@'%mydomain.com' REQUIRE SSL;
```

## 15.3.8. Semisynchronous Replication

MySQL 5.5 supports an interface to semisynchronous replication in addition to the built-in asynchronous replication. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks after the commit is done and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave after having performed a commit), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks after committing each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to com-

plete a transaction.

- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits after commit only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity. When a commit returns successfully, it is known that the data exists in at least two places (on the master and at least one slave). If the master commits but a crash occurs while the master is waiting for acknowledgment from a slave, it is possible that the transaction may not have reached any slave.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

### 15.3.8.1. Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:

- `rpl_semi_sync_master_enabled`

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 1.

- `rpl_semi_sync_master_timeout`

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_xxx` system variables are described at [Section 5.1.3, “Server System Variables”](#).

- Status variables enable semisynchronous replication monitoring. Some examples:

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_XXX` status variables are described at [Section 5.1.5, “Server Status Variables”](#).

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

### 15.3.8.2. Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.
- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working. For information on creating a master/slave relationship, see [Section 15.1.1, “How to Set Up Replication”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

The semisynchronous replication plugins are included with MySQL distributions.

Unpack the component distribution, which contains files for the master side and the slave side.

Install the component files in the plugin directory of the appropriate server. Install the `semisync_master*` files in the plugin directory of the master server. Install the `semisync_slave*` files in the plugin directory of each slave server. The location of the plugin directory is available as the value of the server's `plugin_dir` system variable.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous.

On the master:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
mysql> INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

The preceding commands use a plugin file name suffix of `.so`. A different suffix might apply on your system. If you are not sure about the plugin file name, look for the plugins in the server's plugin directory.

If an attempt to install a plugin results in an error on Linux similar to that shown here, you will need to install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so' (errno: 22 libimf.so: cannot open
shared object file: No such file or directory)
```

You can obtain `libimf` from <http://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
mysql> SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
mysql> SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
mysql> SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 1.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
mysql> STOP SLAVE IO_THREAD; START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

### 15.3.8.3. Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

## 15.4. Replication Notes and Tips

### 15.4.1. Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.5 (or later), you cannot replicate to a slave that uses MySQL 5.1 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.5 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 18.7, “Binary Logging of Stored Programs”](#). For more information about row-based logging and row-based replication, see [Section 5.2.4.1, “Binary Logging Formats”](#), and [Section 15.1.2, “Replication Formats”](#).

For additional information specific to replication and InnoDB, see [Section 13.3.5.5, “InnoDB and MySQL Replication”](#). For information relating to replication with MySQL Cluster, see [Section 16.6, “MySQL Cluster Replication”](#).

#### 15.4.1.1. Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. In MySQL 5.5, such statements are marked as unsafe. (Bug #45677)
- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section C.5.7.1, “Problems with ALTER TABLE”](#).

### 15.4.1.2. Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the slave MySQL version. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.
- If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values. This is true whether you are using statement-based or row-based replication.
- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 15.4.1.3. Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 15.4.1.4, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.5, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

### 15.4.1.4. Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 12.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL handles the statement in a version-dependent way.

In MySQL 5.1 before 5.1.51 and in MySQL 5.5 before 5.5.6 (this is the original behavior):

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.1 as of 5.1.51:

- `STATEMENT` or `MIXED` format: The statement is logged as the equivalent pair of `CREATE TABLE` and `INSERT INTO ... SELECT` statements.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.5 as of 5.5.6:

- Nothing is inserted or logged.

These version dependencies arise due to a change in MySQL 5.5.6 in handling of `CREATE TABLE ... SELECT` not to insert rows if the destination table already exists, and a change made in MySQL 5.1.51 to preserve forward compatibility in replication of such statements from a 5.1 master to a 5.5 slave. For details, see [Section 12.1.17.1, “CREATE TABLE ... SELECT Syntax”](#).

When using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. This is due to the fact that MySQL 5.6 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement—a change in behavior from previous versions of MySQL, which permitted these statements to do so. To keep this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 5.6 (or later). (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement will fail there as well, following the upgrade, unless the statement is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events (or possibly row-update events), rather than as the entire `CREATE TABLE ... SELECT` statement.

#### 15.4.1.5. Replication of `DROP ... IF EXISTS` Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master. (Bug #13684)

#### 15.4.1.6. Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

##### 15.4.1.6.1. Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

(This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (  
  c1 INT,  
  c2 INT,  
  c3 INT  
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c3;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

### Note

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 10.1.4, “Data Type Default Values”](#)).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);  
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise Error 1532 (`ER_BINLOG_ROW_RBR_TO_SBR`) because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);  
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise Error 1532 because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);  
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);  
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise Error 1532 because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise Error 1532 because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

### 15.4.1.6.2. Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

#### Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

**Row-based replication: attribute promotion and demotion.** Formerly, due to the fact that in row-based replication changes rather than statements are replicated, and that these changes are transmitted using formats that do not always map directly to MySQL server column data types, you could not replicate between different subtypes of the same general type (for example, from `TINYINT` to `BIGINT`, both `INT` subtypes). However, beginning with MySQL 5.5.3, MySQL Replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

**Type conversion modes (`slave_type_conversions` variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

Mode	Effect
<code>ALL_LOSSY</code>	In this mode, type conversions that would mean loss of information are permitted.

Mode	Effect
	This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.
<code>ALL_NON_LOSSY</code>	This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the source type has a wider range than the target type.  Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code> , then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code> , or <code>CHAR(25)</code> to <code>VARCHAR(20)</code> ) causes the slave to stop with an error.
<code>ALL_LOSSY, ALL_NON_LOSSY</code>	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
[empty]	When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.  This mode is the default.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For insuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $M' \Rightarrow M$  and  $D' \Rightarrow D$  is non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 11.18.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* characters of the string on the slave, where *N* is the width of the target column.

### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* bytes of the string on the slave, where *N* is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where  $M' > M$ , the most significant bits of the `BIT(M')` column are cleared (set to zero) and the *M* bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where  $M' < M$ , the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

**Replication type conversions in MySQL 5.5.3 and earlier.** Prior to MySQL 5.5.3, with row-based binary logging, you could not replicate between different `INT` subtypes, such as from `TINYINT` to `BIGINT`, because changes to columns of these types were represented differently from one another in the binary log when using row-based logging. (However, you could replicate from `BLOB` to `TEXT` using row-based replication because changes to `BLOB` and `TEXT` columns were represented using the same format in the binary log.)

Supported conversions for attribute promotion when using row-based replication prior to MySQL 5.5.3 are shown in the following table:

From (Master)	To (Slave)
<code>BINARY</code>	<code>CHAR</code>
<code>BLOB</code>	<code>TEXT</code>
<code>CHAR</code>	<code>BINARY</code>
<code>DECIMAL</code>	<code>NUMERIC</code>
<code>NUMERIC</code>	<code>DECIMAL</code>
<code>TEXT</code>	<code>BLOB</code>
<code>VARBINARY</code>	<code>VARCHAR</code>
<code>VARCHAR</code>	<code>VARBINARY</code>

### Note

In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you could replicate from a `CHAR(10)` column on the master to a column that used `BINARY(10)` or `BINARY(25)` on the slave, but you could not replicate from a `CHAR(10)` column on the master to `BINARY(5)` column on the slave.

Any unique index (including primary keys) having a prefix must use a prefix of the same length on both master and slave; in such cases, differing prefix lengths are disallowed. It is possible to use a non-unique index whose prefix length differs between master and slave, but this can cause serious performance issues, particularly when the prefix used on the master is longer. This is due to the fact that 2 unique prefixes of a given length may no longer be unique at a shorter length; for example, the words *catalogue* and *catamount* have the 5-character prefixes *catal* and *catam*, respectively, but share the same 4-character prefix (*cata*). This can lead to queries that use such indexes executing less efficiently on the slave, when a shorter prefix is employed in the slave's definition of the same index than on the master.

For `DECIMAL` and `NUMERIC` columns, both the mantissa (*M*) and the number of decimals (*D*) must be the same size or larger on the slave as compared with the master. For example, replication from a `NUMERIC(5,4)` to a `DECIMAL(6,4)` worked, but not from a `NUMERIC(5,4)` to a `DECIMAL(5,3)`.

Prior to MySQL 5.5.3, MySQL replication did not support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

- `INT` (including `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`).

Promotion between `INT` subtypes—for example, from `SMALLINT` to `BIGINT`—was also not supported prior to MySQL 5.5.3.

- `SET` or `ENUM`.
- `FLOAT` or `DOUBLE`.

- All of the data types relating to dates, times, or both: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

### 15.4.1.7. Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.6, “Server SQL Modes”](#).

### 15.4.1.8. Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CREATE FUNCTION`
  - `DROP FUNCTION`
  - `CREATE TRIGGER`
  - `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

#### Note

Attempting to replicate invoked features using statement-based replication produces the warning `STATEMENT IS NOT SAFE TO LOG IN STATEMENT FORMAT`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 19.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), and [Section 12.7.5.19, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLED`, where *event\_name* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *master\_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

### 15.4.1.9. Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 11.2, “Type Conversion in Expression Evaluation”](#), and [Section C.5.5.8, “Problems with Floating-Point Values”](#).

### 15.4.1.10. Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 12.7.6.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 15.4.1.11. Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 15.1.2, “Replication Formats”](#)).

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #28086) Beginning with MySQL 5.5.1, the same is true for `VERSION()`. (Bug #47995)

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

Beginning with MySQL 5.5.1, `SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995)

See also [Section 15.4.1.28, “Replication and Time Zones”](#).

- The following restriction applies to statement-based replication only, not to row-based replication. The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES (GET_LOCK(...))`.

Beginning with MySQL 5.5.1, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #47995)

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

#### 15.4.1.12. Replication and `LIMIT`

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

Currently, when using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

#### 15.4.1.13. Replication and `LOAD DATA INFILE`

The `LOAD DATA INFILE` statement was not always replicated correctly to a slave running MySQL 5.5.0 or earlier from a master running MySQL 4.0 or earlier. When using statement-based replication, the `LOAD DATA INFILE` statement `CONCURRENT` option was not replicated. This issue was fixed in MySQL 5.5.0. This issue does not have any impact on `CONCURRENT` option handling when using row-based replication in MySQL 5.1 or later. (Bug #34628)

In MySQL 5.5.6 and later, `LOAD DATA INFILE` is considered unsafe (see [Section 15.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)). It causes a warning when using statement-based logging format, and is logged using row-based format

when using mixed-format logging.

#### 15.4.1.14. Replication and the Slow Query Log

Replication slaves do not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. This is a known issue. (Bug #23300)

#### 15.4.1.15. Replication and `REPAIR TABLE`

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

#### 15.4.1.16. Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 5.1.3, “Server System Variables”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 15.4.1.19, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. The default value of `sync_relay_log_info` is 0, which does not cause writes to be forced to disk; the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

#### 15.4.1.17. Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

#### 15.4.1.18. Replication and `MEMORY` Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

See [Section 13.6, “The `MEMORY` Storage Engine”](#), for more information about `MEMORY` tables.

### 15.4.1.19. Replication and Temporary Tables

This section does not apply when row-based replication is in use because in that case temporary tables are not replicated. It does apply with mixed-format replication for statements involving temporary tables that can be logged safely using statement-based format. See [Section 15.1.2.2, “Usage of Row-Based Logging and Replication”](#).

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

### 15.4.1.20. Replication of the `mysql` System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

### 15.4.1.21. Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 15.4.1.12, “Replication and `LIMIT`”](#), for a detailed discussion of these.

### 15.4.1.22. Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named

`current_user` on a 4.0 master that is replicating to a 4.1 or higher slave because `CURRENT_USER` is a reserved word beginning in MySQL 4.1. Replication can fail in such cases with Error 1064 `YOU HAVE AN ERROR IN YOUR SQL SYNTAX...`, even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 8.2, “Schema Object Names”](#).

### 15.4.1.23. SET PASSWORD and Row-Based Replication

Row-based replication of `SET PASSWORD` statements from a MySQL 5.1 master to a MySQL 5.5 slave did not work correctly prior to MySQL 5.1.53 on the master and MySQL 5.5.7 on the slave (see Bug #57098, Bug #57357).

### 15.4.1.24. Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

### 15.4.1.25. Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 5.1.6, “Server SQL Modes”](#).

### 15.4.1.26. Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the slave SQL thread fails to execute

a transaction because of an [InnoDB deadlock](#) or because it exceeded the [InnoDB innodb\\_lock\\_wait\\_timeout](#) value, or the [NDBCLUSTER TransactionDeadlockDetectionTimeout](#) or [TransactionInactiveTimeout](#) value, the slave automatically retries the transaction [slave\\_transaction\\_retries](#) times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.1.5](#), “[Server Status Variables](#)”.

### 15.4.1.27. Replication and **TIMESTAMP**

Older versions of MySQL (prior to 4.1) differed significantly in several ways in their handling of the **TIMESTAMP** data type from what is supported in MySQL versions 5.5 and newer; these include syntax extensions which are deprecated in MySQL 5.1, and that no longer supported in MySQL 5.5. This this can cause problems (including replication failures) when replicating between MySQL Server versions, if you are using columns that are defined using the old **TIMESTAMP(N)** syntax. See [Section 2.11.1.1](#), “[Upgrading from MySQL 5.1 to 5.5](#)”, for more information about the differences, how they can impact MySQL replication, and what you can do if you encounter such problems.

### 15.4.1.28. Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the **TZ** environment variable. See also [Section 15.4.1.11](#), “[Replication and System Functions](#)”.

If the master is MySQL 4.1 or earlier, both master and slave should also use the same default connection time zone. That is, the `--default-time-zone` parameter should have the same value for both master and slave.

`CONVERT_TZ(..., ..., @@session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

### 15.4.1.29. Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

As of MySQL 5.5.2, the server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.** To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. Prior to MySQL 5.5.6, a statement that changed both nontransactional and transactional tables was considered “mixed”. Beginning with MySQL 5.5.6, a statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a mixed statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

Beginning with MySQL 5.5.6, a mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a transactional table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

Also beginning with MySQL 5.5.6, any mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_trans_update` is OFF

For more information, see [Section 15.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

### Note

A mixed statement is unrelated to mixed binary logging format.

Before MySQL 5.5.2, the rules for binary logging are similar to those just described, except that there is no `binlog_direct_non_transactional_updates` system variable to affect logging of transactional statements. Thus, the server immediately logs only the initial nontransactional statements in a transaction and caches the rest until commit time.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

Beginning with MySQL 5.5.0, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases (beginning with MySQL 5.5.0), an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** Beginning with MySQL 5.5.3, the `binlog_format` system variable is read-only as long as a transaction is in progress. (Bug #47863)

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. In MySQL 5.5, this true is even for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

## 15.4.1.30. Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 5.5 marks such statements as unsafe. (Bug #45677)

## 15.4.1.31. Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

### 15.4.1.32. Replication and `TRUNCATE TABLE`

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 12.1.33, “TRUNCATE TABLE Syntax”](#) governing such tables. (Bug #36763)

### 15.4.1.33. Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;  
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;  
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 15.1.2, “Replication Formats”](#).

In MySQL 5.5, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

### Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

It is strongly recommended that you always use the same setting for the `lower_case_table_names` system variable on both master and slave. In particular, when a case-sensitive file system is used, setting this variable to 1 on the slave, but to a different value on the master, can cause two types of problems: Names of databases are not converted to lowercase; in addition, when using row-based replication names of tables are also not converted. Either of these problems can cause replication to fail. This is a known issue, which is fixed in MySQL 5.6.

## 15.4.2. Replication Compatibility Between MySQL Versions

MySQL supports replication from one major version to the next higher major version. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so on.

However, one may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, in MySQL 5.5, `CREATE TABLE ... SELECT` statements are permitted to change tables other than the one being created, but are no longer allowed to do so in MySQL 5.6 (see [Section 15.4.1.4, “Replication of CREATE TABLE ... SELECT Statements”](#)).

The use of more than 2 MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to major versions, but to minor versions within the same major version as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.5.1, MySQL 5.5.2, and MySQL 5.5.4 concurrently, although you could use any 2 of these releases together.

In some cases, it is also possible to replicate between a master and a slave that is more than one major version newer than the master.

However, there are known issues with trying to replicate from a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

### Important

It is strongly recommended to use the most recent release available within a given MySQL major version because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a major version of MySQL to GA (production) releases when the latter become available for that major version.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, [LOAD DATA INFILE](#), and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

This also has significant implications for upgrading replication servers; see [Section 15.4.3, “Upgrading a Replication Setup”](#), for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.5 or later master to a slave older than MySQL 5.1.5.

For more information about row-based replication, see [Section 15.1.2, “Replication Formats”](#).

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 15.4.1, “Replication Features and Issues”](#).

## 15.4.3. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.5. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.5 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.5.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.5.x version, restart it, and restart replication. The 5.5 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.5 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.5.x release as the slaves, and restart it. The 5.5 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.5 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.5 format. These too are recognized by the 5.5 slaves.

In other words, when upgrading to MySQL 5.5, the slaves must be MySQL 5.5 before you can upgrade the master to 5.5. Note that downgrading from 5.5 to older versions does not work so simply: You must ensure that any 5.5 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See [Section 15.1.2, “Replication Formats”](#).

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, will be detailed at [Section 2.11.1.1, “Upgrading from MySQL 5.1 to 5.5”](#). It is safest to perform these operations separately on the slaves and the master, and to disable rep-

lication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

## 15.4.4. Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 15.2.1, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.
  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
  - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 15.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 15.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then

make the slave's table identical to the master's and run `START SLAVE`.

2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;  
mysql> START SLAVE;
```

The value of *N* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 12.4.2.4, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 15.4.5. How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the master
  - All binary log files from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

---

## Chapter 16. MySQL Cluster NDB 7.2

### Table of Contents

16.1. MySQL Cluster Overview .....	1640
16.1.1. MySQL Cluster Core Concepts .....	1641
16.1.2. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions .....	1643

This chapter contains information about *MySQL Cluster*, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Recent releases of MySQL Cluster use version 7 of the **NDBCLUSTER** storage engine (also known as **NDB**) to enable running several computers with MySQL servers and other software in a cluster; the latest releases available for production use incorporate **NDB** version 7.2.

Support for the **NDBCLUSTER** storage engine is not included in the standard MySQL Server 5.5 binaries built by Oracle. Instead, users of MySQL Cluster binaries from Oracle should upgrade to the most recent binary release of MySQL Cluster for supported platforms—these include RPMs that should work with most Linux distributions. MySQL Cluster users who build from source should use the sources provided for MySQL Cluster. (Locations where the sources can be obtained are listed later in this section.)

This chapter contains information about MySQL Cluster NDB 7.2 releases through 5.5.20-ndb-7.2.5. Currently, the MySQL Cluster NDB 7.2 release series is Generally Available (GA), as is MySQL Cluster NDB 7.1. MySQL Cluster NDB 7.0 and MySQL Cluster NDB 6.3 are previous GA release series; although they are still supported, we recommend that new deployments use MySQL Cluster NDB 7.2. For information about MySQL Cluster NDB 7.1, MySQL Cluster NDB 7.0, and previous versions of MySQL Cluster, see [MySQL Cluster NDB 6.X/7.X](#), in the *MySQL 5.1 Manual*.

**Supported Platforms.** MySQL Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <http://www.mysql.com/support/supportedplatforms/cluster.html>.

**Availability.** MySQL Cluster binary and source packages are available for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

**MySQL Cluster release numbers.** MySQL Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.5 series of releases. In this *Manual* and other MySQL documentation, we identify these and later MySQL Cluster releases employing a version number that begins with “NDB”. This version number is that of the **NDBCLUSTER** storage engine used in the release, and not of the MySQL server version on which the MySQL Cluster release is based.

**Version strings used in MySQL Cluster software.** The version string displayed by MySQL Cluster programs uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

*mysql\_server\_version* represents the version of the MySQL Server on which the MySQL Cluster release is based. For all MySQL Cluster NDB 6.x and 7.x releases, this is “5.1”. *ndb\_engine\_version* is the version of the **NDB** storage engine used by this release of the MySQL Cluster software. You can see this format used in the **mysql** client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.1.61-ndb-7.1.20 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 5.1.61-ndb-7.1.20
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.5.20-ndb-7.2.5, Nodegroup: 0, Master)
id=2 @10.0.10.8 (5.5.20-ndb-7.2.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3 @10.0.10.2 (5.5.20-ndb-7.2.5)

[mysqld(API)] 2 node(s)
id=4 @10.0.10.10 (5.5.20-ndb-7.2.5)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the MySQL Cluster release was branched and the version of the `NDBCLUSTER` storage engine used. For example, the full version string for MySQL Cluster NDB 7.2.4 (the first MySQL Cluster production release based on MySQL Server 5.5) is `mysql-5.5.19-ndb-7.2.4`. From this we can determine the following:

- Since the portion of the version string preceding “`-ndb-`” is the base MySQL Server version, this means that MySQL Cluster NDB 7.2.4 derives from the MySQL 5.5.19, and contains all feature enhancements and bugfixes from MySQL 5.5 up to and including MySQL 5.5.19.
- Since the portion of the version string following “`-ndb-`” represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, MySQL Cluster NDB 7.2.4 uses version 7.2.4 of the `NDBCLUSTER` storage engine.

New MySQL Cluster releases are numbered according to updates in the `NDB` storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, MySQL Cluster NDB 7.2.4 (as previously noted) is based on MySQL 5.5.19, while MySQL Cluster NDB 7.2.0 was based on MySQL 5.1.51 (version string: `mysql-5.1.51-ndb-7.2.0`).

**Compatibility with standard MySQL 5.5 releases.** While many standard MySQL schemas and applications can work using MySQL Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using MySQL Cluster (see [Section 16.1.6, “Known Limitations of MySQL Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and MySQL Cluster codebases diverge considerably, so that the standard `mysqld` cannot function as a drop-in replacement for the version of `mysqld` supplied with MySQL Cluster.

**MySQL Cluster development source trees.** MySQL Cluster development trees can also be accessed from <https://code.launchpad.net/~mysql/>:

The MySQL Cluster development sources maintained at <https://code.launchpad.net/~mysql/> are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see [Section 2.9.3, “Installing MySQL from a Development Source Tree”](#).

### Note

As with MySQL Server 5.5, MySQL Cluster NDB 7.2 is built using `CMake`.

Currently, MySQL Cluster NDB 7.0, MySQL Cluster NDB 7.1, and MySQL Cluster NDB 7.2 releases are all Generally Available (GA), although we recommend that new deployments use MySQL Cluster NDB 7.2. MySQL Cluster NDB 6.1, MySQL Cluster NDB 6.2, and MySQL Cluster NDB 6.3, are no longer in active development. For an overview of major features added in MySQL Cluster NDB 7.2, see [Section 16.1.4, “MySQL Cluster Development History”](#). For an overview of major features added in past MySQL Cluster releases through MySQL Cluster NDB 7.1, see [MySQL Cluster Development History](#).

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL Web site at <http://www.mysql.com/products/cluster/>.

**Additional Resources.** More information may be found in the following places:

- For answers to some commonly asked questions about MySQL Cluster, see [Section B.10, “MySQL FAQ: MySQL 5.5 and MySQL Cluster”](#).
- The MySQL Cluster mailing list: <http://lists.mysql.com/cluster>.

- The MySQL Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many MySQL Cluster users and developers blog about their experiences with MySQL Cluster, and make feeds of these available through [PlanetMySQL](#).

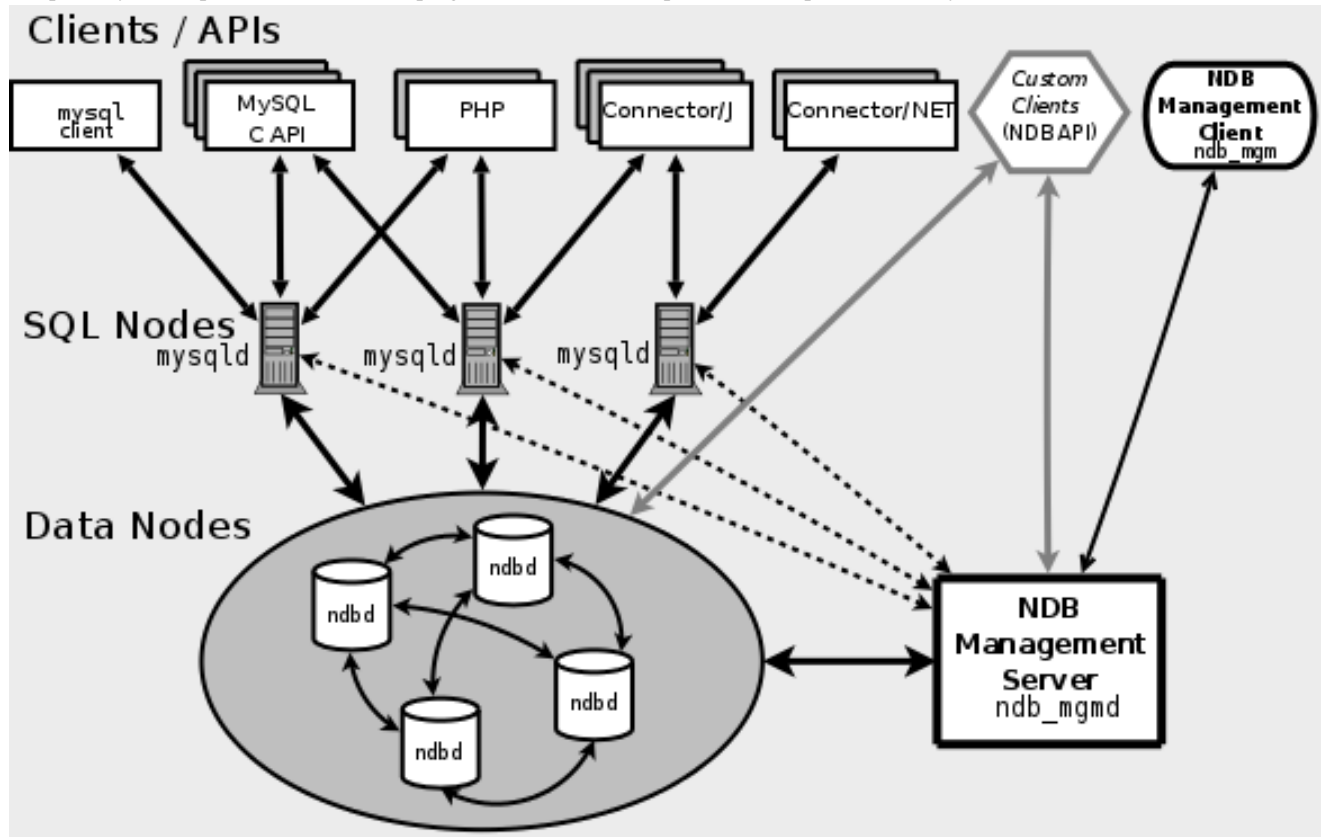

## 16.1. MySQL Cluster Overview

*MySQL Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for “Network DataBase”). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of one or more MySQL servers with the **NDB** storage engine.

A MySQL Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in a MySQL Cluster is shown here:

All these programs work together to form a MySQL Cluster (see [Section 16.4, “MySQL Cluster Programs”](#)). When data is stored by the **NDB** storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although a MySQL Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.5 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to a MySQL Cluster cannot use the [NDB](#) storage engine and cannot access any MySQL Cluster data.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#)). Rolling restarts are also used as part of the process of adding new data nodes online (see [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in a MySQL Cluster, and how they handle and store MySQL Cluster data, see [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Backing up and restoring MySQL Cluster databases can be done using the [NDB](#)-native functionality found in the MySQL Cluster management client and the `ndb_restore` program included in the MySQL Cluster distribution. For more information, see [Section 16.5.3, “Online Backup of MySQL Cluster”](#), and [Section 16.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#), for more information.

MySQL Cluster nodes can use a number of different transport mechanisms for inter-node communications, including TCP/IP using standard 100 Mbps or faster Ethernet hardware. It is also possible to use the high-speed *Scalable Coherent Interface* (SCI) protocol with MySQL Cluster, although this is not required to use MySQL Cluster. SCI requires special hardware and software; see [Section 16.3.5, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about SCI and using it with MySQL Cluster.

## 16.1.1. MySQL Cluster Core Concepts

[NDBCLUSTER](#) (also known as [NDB](#)) is an in-memory storage engine offering high-availability and data-persistence features.

The [NDBCLUSTER](#) storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's [NDB](#) storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#)). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 16.4.2, “ndbd — The MySQL Cluster Data Node Daemon”](#)) or `ndbmtdd` (see [Section 16.4.3, “ndbmtdd — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#)).

MySQL Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to MySQL Cluster as an *in-memory* database). However, some MySQL Cluster data can be stored on disk; see [Section 16.5.11, “MySQL Cluster Disk Data Tables”](#), for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the [NDBCLUSTER](#) storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses MySQL Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

### Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with MySQL Cluster, see [Using Connector/J with MySQL Cluster](#).

**NDB client programs.** Client programs can be written that access MySQL Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see [The NDB API](#).

Beginning with MySQL Cluster NDB 7.1, NDB-specific Java applications can also be written for MySQL Cluster, using the *MySQL Cluster Connector for Java*. This MySQL Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. Support is also provided in MySQL Cluster NDB 7.1 and later for *ClusterJPA*, an OpenJPA implementation for MySQL Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See [Java and MySQL Cluster](#), and [The ClusterJ API and Data Object Model](#), for more information.

The Memcache API for MySQL Cluster, implemented as the loadable `ndbmemcache` storage engine for memcached version 1.6 and later, is available beginning with MySQL Cluster NDB 7.2.2. This API can be used to provide a persistent MySQL Cluster data store, accessed using the memcache protocol.

The standard `memcached` caching engine is included in the MySQL Cluster NDB 7.2 distribution (7.2.2 and later). Each `memcached` server has direct access to data stored in MySQL Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see [Section 16.5.15, “ndbmemcache”](#).

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with MySQL Cluster (see [Section 16.4.5, “ndb\\_mgm — The MySQL Cluster Management Client”](#)). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see [The MGM API](#).

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex MySQL Cluster management tasks, such as restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to MySQL Cluster. MySQL Cluster Manager 1.1 provides support for adding data nodes online. See the [MySQL Cluster Manager User Manual](#), for more information.

**Event logs.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 16.5.5, “Event Reports Generated in MySQL Cluster”](#). Event logs are of the two types listed here:

- *Cluster log:* Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log:* A separate log which is also kept for each individual node.

### Note

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to MySQL Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP):* This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
- *Global Checkpoint (GCP):* A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

## 16.1.2. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**(Data) Node.** An `ndbd` process, which stores a *replica* —that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NoOfReplicas
```

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NoOfReplicas`, see [Section 16.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

### Note

All node groups in a MySQL Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running MySQL Cluster; see [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#), for more information.

**Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

**NDB and user-defined partitioning.** MySQL Cluster normally partitions `NDBCLUSTER` tables automatically. However, in MySQL 5.1 and later MySQL Cluster releases, it is possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only `KEY` and `LINEAR KEY` partitioning schemes can be used with `NDBCLUSTER` tables.
2. When using `ndbd`, the maximum number of partitions that may be defined explicitly for any `NDBCLUSTER` table is  $8 * [\text{number of node groups}]$ . (The number of node groups in a MySQL Cluster is determined as discussed previously in this section.)

When using `ndbmt`, this maximum is also affected by the number of local query handler threads, which is determined by the value of the `MaxNoOfExecutionThreads` configuration parameter. In such cases, the maximum number of partitions that may be defined explicitly for an NDB table is equal to  $4 * \text{MaxNoOfExecutionThreads} * [\text{number of node groups}]$ .

See [Section 16.4.3, “ndbmt — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

For more information relating to MySQL Cluster and user-defined partitioning, see [Section 16.1.6, “Known Limitations of MySQL Cluster”](#), and [Section 17.5.2, “Partitioning Limitations Relating to Storage Engines”](#).

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary

replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an **X**); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

### 16.1.3. MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see [Section 16.5.11, “MySQL Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other MySQL Cluster processes are relatively small.

The software requirements for MySQL Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL 5.1.61-ndb-7.0.31 or 5.1.61-ndb-7.1.20 to have MySQL Cluster support. It is not strictly necessary to compile MySQL yourself merely to be able to use MySQL Cluster. We assume that you are using the binaries appropriate to your platform, available from the MySQL Cluster software downloads page at <http://dev.mysql.com/downloads/cluster/>.

For communication between nodes, MySQL Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between MySQL Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your MySQL Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See [Section 16.5.10.1, “MySQL Cluster Security and Networking Issues”](#), for more information.

- **Efficiency.** Setting up a MySQL Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to MySQL Cluster data, it also ensures that MySQL Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** MySQL Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, MySQL Cluster uses heartbeat and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, a MySQL Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for MySQL Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100  $\mu$ s), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where MySQL Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

**SCI support.** It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See [Section 16.3.5, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about this protocol and its use with MySQL Cluster.

## 16.1.4. MySQL Cluster Development History

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL MySQL Cluster NDB 7.2, as compared to MySQL Cluster NDB 7.1 and earlier releases. Changes and features most likely to be of interest are shown in the following table:

**MySQL Cluster NDB 7.2**

MySQL Cluster NDB 7.2.1 and later MySQL Cluster NDB 7.2 releases are based on MySQL 5.5. For more information about new features in MySQL Server 5.5, see [Section 1.4, “What Is New in MySQL 5.5”](#).

Version 2 binary log row events, to provide support for improvements in MySQL Cluster Replication conflict detection (see next item). A given `mysqld` can be made to use Version 1 or Version 2 binary logging row events with the `--log-bin-use-v1-row-events` option.

Two new “primary wins” conflict detection and resolution functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` for use in replication setups with 2 MySQL Clusters. For more information, see [Section 16.6, “MySQL Cluster Replication”](#).

Distribution of MySQL users and privileges across MySQL Cluster SQL nodes is now supported—see [Section 16.5.13, “Distributed MySQL Privileges for MySQL Cluster”](#).

Improved support for distributed pushed-down joins, which greatly improve performance for many joins that can be executed in parallel on the data nodes.

Default values for a number of data node configuration parameters such as `HeartbeatIntervalDbDb` and `Arbitration-Timeout` have been improved.

Support for the Memcache API using the loadable `ndbmemcache` storage engine. See [Section 16.5.15, “ndbmemcache”](#).

This section contains information about MySQL Cluster NDB 7.2 releases through 5.5.20-ndb-7.2.5, which is currently available for use in production beginning with MySQL Cluster NDB 7.2.4. MySQL Cluster NDB 7.1, MySQL Cluster NDB 7.0, and MySQL Cluster NDB 6.3 are previous GA release series; although these are still supported, we recommend that new deployments use MySQL Cluster NDB 7.2. For information about MySQL Cluster NDB 7.1 and previous releases, see [MySQL Cluster NDB 6.X/7.X](#), in the *MySQL 5.1 Manual*.

**16.1.4.1. MySQL Cluster Development in MySQL Cluster NDB 7.2**

The following improvements to MySQL Cluster have been made in MySQL Cluster NDB 7.2.

- Based on MySQL Server 5.5.** Previous MySQL Cluster release series, including MySQL Cluster NDB 7.1, used MySQL 5.1 as a base. Beginning with MySQL Cluster NDB 7.2.1, MySQL Cluster NDB 7.2 is based on MySQL Server 5.5, so that MySQL Cluster users can benefit from MySQL 5.5's improvements in scalability and performance monitoring. As with MySQL 5.5, MySQL Cluster NDB 7.2.1 and later use `CMake` for configuring and building from source in place of GNU autotools (used in MySQL 5.1 and MySQL Cluster releases based on MySQL 5.1). For more information about changes and improvements in MySQL 5.5, see [Section 1.4, “What Is New in MySQL 5.5”](#).
- Conflict detection using GCI Reflection.** MySQL Cluster Replication implements a new “primary wins” conflict detection and resolution mechanism. *GCI Reflection* applies in two-cluster circulation “active-active” replication setups, tracking the order in which changes are applied on the MySQL Cluster designated as primary relative to changes originating on the other MySQL Cluster (referred to as the secondary). This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict. Two new conflict detection functions are added: When using `NDB$EPOCH()`, rows that are out of sync on the secondary are realigned with those on the primary; with `NDB$EPOCH_TRANS()`, this realignment is applied to transactions. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).
- Version 2 binary log row events.** A new format for binary log row events, known as Version 2 binary log row events, provides support for improvements in MySQL Cluster Replication conflict detection (see previous item) and is intended to facilitate further improvements in MySQL Replication. You can cause a given `mysqld` use Version 1 or Version 2 binary logging row events with the `--log-bin-use-v1-row-events` option. For backwards compatibility, Version 2 binary log row events are also available in MySQL Cluster NDB 7.0 (7.0.27 and later) and MySQL Cluster NDB 7.1 (7.1.16 and later). However, MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 continue to use Version 1 binary log row events as the default, whereas the default in MySQL Cluster NDB 7.2.1 and later is use Version 2 row events for binary logging.
- Distribution of MySQL users and privileges.** Automatic distribution of MySQL users and privileges across all SQL nodes in a given MySQL Cluster is now supported. To enable this support, you must first import an SQL script `share/mysql/ndb_dist_priv.sql` that is included with the MySQL Cluster NDB 7.2 distribution. This script creates several stored procedures which you can use to enable privilege distribution and perform related tasks.

When a new MySQL Server joins a MySQL Cluster where privilege distribution is in effect, it also participates in the privilege distribution automatically.

Once privilege distribution is enabled, all changes to the grant tables made on any `mysqld` attached to the cluster are immediately

available on any other attached MySQL Servers. This is true whether the changes are made using `CREATE USER`, `GRANT`, or any of the other statements described elsewhere in this Manual (see [Section 12.7.1, “Account Management Statements”](#).) This includes privileges relating to stored routines and views; however, automatic distribution of the views or stored routines themselves is not currently supported.

For more information, see [Section 16.5.13, “Distributed MySQL Privileges for MySQL Cluster”](#).

- **Distributed pushed-down joins.** Many joins can now be pushed down to the NDB kernel for processing on MySQL Cluster data nodes. Previously, a join was handled in MySQL Cluster by means of repeated accesses of `NDB` by the SQL node; however, when pushed-down joins are enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join, leading to greatly improved performance of join processing.

It is possible to determine when joins can be pushed down to the data nodes by examining the join with `EXPLAIN`. A number of new system status variables (`Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`) and additions to the `counters` table (in the `ndbinfo` information database) can also be helpful in determining when and how well joins are being pushed down.

More information and examples are available in the description of the `ndb_join_pushdown` server system variable. See also the description of the status variables referenced in the previous paragraph, as well as [Section 16.5.9.3, “The `ndbinfo` counters Table”](#).

- **Improved default values for data node configuration parameters.** In order to provide more resiliency to environmental issues and better handling of some potential failure scenarios, and to perform more reliably with increases in memory and other resource requirements brought about by recent improvements in join handling by `NDB`, the default values for a number of MySQL Cluster data node configuration parameters have been changed. The parameters and changes are described in the following list:

- `HeartbeatIntervalDbDb`: Default increased from 1500 ms to 5000 ms.
- `ArbitrationTimeout`: Default increased from 3000 ms to 7500 ms.
- `TimeBetweenEpochsTimeout`: Now effectively disabled by default (default changed from 4000 ms to 0).
- `SharedGlobalMemory`: Default increased from 20 MB to 128 MB.
- `MaxParallelScansPerFragment`: Default increased from 32 to 256.

In addition, the value computed for `MaxNoOfLocalScans` when this parameter is not set in `config.ini` has been increased by a factor of 4.

- **Fail-fast data nodes.** Beginning with MySQL Cluster NDB 7.2.1, data nodes handle corrupted tuples in a fail-fast manner by default. This is a change from previous versions of MySQL Cluster where this behavior had to be enabled explicitly by enabling the `CrashOnCorruptedTuple` configuration parameter. In MySQL Cluster NDB 7.2.1 and later, this parameter is enabled by default and must be explicitly disabled, in which case data nodes merely log a warning whenever they detect a corrupted tuple.
- **Memcache API support (`ndbmemcache`).** The Memcached server is a distributed in-memory caching server that uses a simple text-based protocol. It is often employed with key-value stores. The Memcache API for MySQL Cluster, available beginning with MySQL Cluster NDB 7.2.2, is implemented as a loadable storage engine for memcached version 1.6 and later. This API can be used to access a persistent MySQL Cluster data store employing the memcache protocol. It is also possible for the `memcached` server to provide a strictly defined interface to existing MySQL Cluster tables.

Each memcache server can both cache data locally and access data stored in MySQL Cluster directly. Cacheing policies are configurable. For more information, see [Section 16.5.15, “`ndbmemcache`”](#).

### 16.1.5. MySQL Server using `InnoDB` Compared with MySQL Cluster

MySQL Server offers a number of choices in storage engines. Since both `NDBCLUSTER` and `InnoDB` can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in MySQL Cluster. They see `NDB` as a possible alternative or upgrade to the default `InnoDB` storage engine in MySQL 5.5. While `NDB` and `InnoDB` share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for MySQL Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the `NDB` storage engine used by MySQL Cluster NDB 7.2 with `InnoDB`

used in MySQL 5.5. The next few sections provide a technical comparison. In many instances, decisions about when and where to use MySQL Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for **NDB** as opposed to **InnoDB** backends.

Recent MySQL Cluster NDB 7.2 releases use a **mysqld** based on MySQL 5.5, including support for **InnoDB** 1.1. While it is possible to use **InnoDB** tables with MySQL Cluster, such tables are not clustered. It is also not possible to use programs or libraries from a MySQL Cluster NDB 7.2 distribution with MySQL Server 5.5, or the reverse.

While it is also true that some types of common business applications can be run either on MySQL Cluster or on MySQL Server (most likely using the **InnoDB** storage engine), there are some important architectural and implementation differences. [Section 16.1.5.1, “Differences Between the NDB and InnoDB Storage Engines”](#), provides a summary of these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see [Section 16.1.5.2, “NDB and InnoDB Workloads”](#). This in turn has an impact on the types of applications that better suited for use with **NDB** or **InnoDB**. See [Section 16.1.5.3, “NDB and InnoDB Feature Usage Summary”](#), for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the **NDB** and **MEMORY** storage engines, see [When to Use MEMORY or MySQL Cluster](#).

See [Chapter 13, Storage Engines](#), for additional information about MySQL storage engines.

### 16.1.5.1. Differences Between the **NDB** and **InnoDB** Storage Engines

The MySQL Cluster **NDB** storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from **InnoDB** in a number of ways. For those unaccustomed to working with **NDB**, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

Feature	<b>InnoDB</b> 1.1	MySQL Cluster <b>NDB</b> 7.2
<i>MySQL Server Version</i>	5.5	5.5
<i>InnoDB Version</i>	<b>InnoDB</b> 1.1	<b>InnoDB</b> 1.1
<i>MySQL Cluster Version</i>	N/A	<b>NDB</b> 7.2
<i>Storage Limits</i>	64TB	3TB  (Practical upper limit based on 48 data nodes with 64GB RAM each; can be increased with disk-based data and BLOBs)
<i>Foreign Keys</i>	Yes	No  (Ignored, as with <b>MyISAM</b> )
<i>Transactions</i>	All standard types	<b>READ COMMITTED</b>
<i>MVCC Non-Blocking Reads</i>	Yes	No
<i>Data Compression</i>	Yes	No  (MySQL Cluster checkpoint and backup files can be compressed)
<i>Large Row Support (&gt; 14K)</i>	Supported for <b>VARBINARY</b> , <b>VARCHAR</b> , <b>BLOB</b> , and <b>TEXT</b> columns	Supported for <b>BLOB</b> and <b>TEXT</b> columns only  (Using these types to store very large amounts of data can lower MySQL Cluster performance)

Feature	InnoDB 1.1	MySQL Cluster NDB 7.2
<i>Replication Support</i>	Asynchronous and semi-synchronous replication using MySQL Replication	Automatic synchronous replication within a MySQL Cluster.  Asynchronous replication between MySQL Clusters, using MySQL Replication
<i>Scaleout for Read Operations</i>	Yes (MySQL Replication)	Yes (Automatic partitioning in MySQL Cluster; MySQL Replication)
<i>Scaleout for Write Operations</i>	Requires application-level partitioning (sharding)	Yes (Automatic partitioning in MySQL Cluster is transparent to applications)
<i>High Availability (HA)</i>	Requires additional software	Yes (Designed for 99.999% uptime)
<i>Node Failure Recovery and Failover</i>	Requires additional software	Automatic  (Key element in MySQL Cluster architecture)
<i>Time for Node Failure Recovery</i>	30 seconds or longer	Typically < 1 second
<i>Real-Time Performance</i>	No	Yes (Low latency)
<i>In-Memory Tables</i>	No	Yes  (Some data can optionally be stored on disk; both in-memory and disk data storage are durable)
<i>NoSQL Access to Storage Engine</i>	Native memcached interface in development (see the MySQL Dev Zone article <a href="#">NoSQL to MySQL with Memcached</a> )	Yes  Multiple APIs, including Memcached, Java, JPA, C++, and HTTP/REST
<i>Concurrent and Parallel Writes</i>	Not supported	Up to 48 writers, optimized for concurrent writes
<i>Conflict Detection and Resolution (Multiple Replication Masters)</i>	No	Yes
<i>Hash Indexes</i>	No	Yes
<i>Online Addition of Nodes</i>	Read-only replicas using MySQL Replication	Yes (all node types)
<i>Online Upgrades</i>	No	Yes
<i>Online Schema Modifications</i>	No	Yes
<i>Real-Time Performance</i>	No	Yes

### 16.1.5.2. NDB and InnoDB Workloads

MySQL Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high

throughput, and low latency. Due to its distributed architecture and multi-node implementation, MySQL Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the **NDB** and **InnoDB** storage engines with regard to some common types of database-driven application workloads are shown in the following table::

Workload	InnoDB	MySQL Cluster (NDB)
<i>High-Volume OLTP Applications</i>	Yes	Yes
<i>DSS Applications (data marts, analytics)</i>	Yes	Limited (Join operations across OLTP datasets not exceeding 3TB in size)
<i>Custom Applications</i>	Yes	Yes
<i>Packaged Applications</i>	Yes	Limited (should be mostly primary key access, without any requirement for foreign keys)
<i>In-Network Telecoms Applications (HLR, HSS, SDP)</i>	No	Yes
<i>Session Management and Caching</i>	Yes	Yes
<i>E-Commerce Applications</i>	Yes	Yes
<i>User Profile Management, AAA Protocol</i>	Yes	Yes

### 16.1.5.3. NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of **InnoDB** with **NDB**, some are clearly more compatible with one storage engine than the other. For example, since **NDB** does not support foreign keys, an application that requires them and cannot be re-engineered to remove this requirement is likely not to be a good match for MySQL Cluster.

The following table shows required supported features for applications according to which of these two storage engines each of them is usually better suited:

Preferred application requirements for InnoDB	Preferred application requirements for NDB
<ul style="list-style-type: none"> <li>Foreign keys</li> <li>Full table scans</li> <li>Very large databases, rows, or transactions</li> <li>Transactions other than <b>READ COMMITTED</b></li> </ul>	<ul style="list-style-type: none"> <li>Write scaling</li> <li>99.999% uptime</li> <li>Online addition of nodes and online schema operations</li> <li>Multiple SQL and NoSQL APIs (see <a href="#">MySQL Cluster APIs: Overview and Concepts</a>)</li> <li>Real-time performance</li> <li>Limited use of <b>BLOB</b> columns</li> </ul>

### 16.1.6. Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in current releases of MySQL Cluster as compared with the features available when using the **MyISAM** and **InnoDB** storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>

[tp://bugs.mysql.com](http://bugs.mysql.com), which we intend to correct in upcoming releases of MySQL Cluster:

- MySQL Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in MySQL Cluster NDB 6.X or 7.X, we will add it to the list.

See [Section 16.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”](#) for a list of issues in MySQL Cluster in MySQL 5.1 that have been resolved in the current version.

### Note

Limitations and other issues specific to MySQL Cluster Replication are described in [Section 16.6.3, “Known Issues in MySQL Cluster Replication”](#).

## 16.1.6.1. Noncompliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with **NDB** tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the **NDB** storage engine or to alter an existing temporary table to use **NDB** fails with the error `TABLE STORAGE ENGINE 'NDBCLUSTER' DOES NOT SUPPORT THE CREATE OPTION 'TEMPORARY'`.
- **Indexes and keys in **NDB** tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an **NDB** table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `SPECIFIED KEY WAS TOO LONG; MAX KEY LENGTH IS 3072 BYTES` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on **NDB** table columns that use any of the **TEXT** or **BLOB** data types.
  - **FULLTEXT indexes.** The **NDB** storage engine does not support **FULLTEXT** indexes, which are possible for **MyISAM** tables only.

However, you can create indexes on **VARCHAR** columns of **NDB** tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column **NOT NULL**, or re-create the index without the **USING HASH** option.
- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an **NDB** column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see [Section 16.1.6.6, “Unsupported or Missing Features in MySQL Cluster”](#), for additional information.)
- **BIT columns.** A **BIT** column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO\_INCREMENT columns.** Like other MySQL storage engines, the **NDB** storage engine can handle a maximum of one **AUTO\_INCREMENT** column per table. However, in the case of a Cluster table with no explicit primary key, an **AUTO\_INCREMENT** column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit **AUTO\_INCREMENT** column unless that column is also declared using the **PRIMARY KEY** option. Attempting to create a table with an **AUTO\_INCREMENT** column that is not the table's primary key, and using the **NDB** storage engine, fails with an error.
- **MySQL Cluster and geometry data types.** Geometry data types (**WKT** and **WKB**) are supported for **NDB** tables. However, spatial

indexes are not supported.

- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating `NDBCLUSTER` tables with user-defined partitioning.** Support for user-defined partitioning for MySQL Cluster in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1) is restricted to `[LINEAR] KEY` partitioning. Beginning with MySQL 5.1.12, using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

**Default partitioning scheme.** As of MySQL 5.1.6, all MySQL Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the `NDBCLUSTER` storage engine is used instead. For additional discussion of these and related issues, see [Section 17.2.5, “KEY Partitioning”](#).

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

**Maximum number of partitions for `NDBCLUSTER` tables.** The maximum number of partitions that can be defined for a `NDB-CLUSTER` table when employing user-defined partitioning is 8 per node group. (See [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information about MySQL Cluster node groups.)

**`DROP PARTITION` not supported.** It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for Cluster tables, but use copying and so are not optimized. See [Section 17.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 12.1.7, “ALTER TABLE Syntax”](#).

- **Row-based replication.** When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the `NDB` storage engine ignores the value of `sql_log_bin`. (Bug #16680)

### 16.1.6.2. Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

A rolling restart of the cluster also frees any memory used by deleted rows. See [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#).

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

#### Note

Recall that `TRUNCATE TABLE` drops and re-creates the table. See [Section 12.1.33, “TRUNCATE TABLE Syntax”](#).

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 16.3.2, “MySQL Cluster Configuration Files”](#).

Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size ([DataMemory](#) and [IndexMemory](#), respectively).

[DataMemory](#) is allocated as 32KB pages. As each [DataMemory](#) page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 16.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters [MaxNoOfConcurrentOperations](#) and [MaxNoOfLocalOperations](#).

#### Note

Bulk loading, [TRUNCATE TABLE](#), and [ALTER TABLE](#) are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by [MaxNoOfOrderedIndexes](#), and the maximum number of ordered indexes per table is 16.
- Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

- The maximum number of data nodes is 48.

A data node must have a node ID in the range of 1 to 49, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

- The total maximum number of nodes in a MySQL Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
- The maximum number of metadata objects in current versions of MySQL Cluster is 20320. This limit is hard-coded.

See [Section 16.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”](#), for more information.

### 16.1.6.3. Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- Transaction isolation level.** The [NDBCLUSTER](#) storage engine supports only the [READ COMMITTED](#) transaction isolation level. ([InnoDB](#), for example, supports [READ COMMITTED](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), and [SERIALIZABLE](#).) See [Section 16.5.3.4, “MySQL Cluster Backup Troubleshooting”](#), for information on how this can affect backing up and restoring Cluster databases.)
- Transactions and [BLOB](#) or [TEXT](#) columns.** [NDBCLUSTER](#) stores only part of a column value that uses any of MySQL's [BLOB](#) or [TEXT](#) data types in the table visible to MySQL; the remainder of the [BLOB](#) or [TEXT](#) is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing [SELECT](#) statements on tables that contain columns of these types:
  - For any [SELECT](#) from a MySQL Cluster table: If the [SELECT](#) includes a [BLOB](#) or [TEXT](#) column, the [READ COMMITTED](#) transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
  - For any [SELECT](#) which uses a unique key lookup to retrieve any columns that use any of the [BLOB](#) or [TEXT](#) data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against [NDB](#) tables having [BLOB](#) or [TEXT](#) columns.

For example, consider the table `t` defined by the following [CREATE TABLE](#) statement:

```
CREATE TABLE t (
  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b INT NOT NULL,
  c INT NOT NULL,
  d TEXT,
```

```
INDEX i(b),
UNIQUE KEY u(c)
) ENGINE = NDB,
```

Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```
SELECT * FROM t WHERE a = 1;
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c FROM t WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.** As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:
  - `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.
  - `DELETE FROM` (even with no `WHERE` clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.
  - **LOAD DATA statements.** `LOAD DATA INFILE` is not transactional when used on `NDB` tables.

### Important

When executing a `LOAD DATA INFILE` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

`LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

- **ALTER TABLE and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is non-transactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the `COUNT()` function.** When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See Bug #31321 for more information.)

## 16.1.6.4. MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `TEMPORARY FAILURE, DISTRIBUTION CHANGED` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 16.1.6.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#).

### 16.1.6.5. Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Number of database objects.** The maximum number of *all* `NDB` database objects in a single MySQL Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 14000 bytes (as of MySQL Cluster NDB 7.0). Each `BLOB` or `TEXT` column contributes  $256 + 8 = 264$  bytes to this total.
- **Number of rows per partition.** A single MySQL Cluster partition can hold a maximum of 46137488 rows. Since the number of partitions is the same as the number of data nodes in the cluster (see [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#)), you can increase the available space for data storage by using more data nodes.

In MySQL Cluster NDB 7.0 and later MySQL Cluster release series (including MySQL Cluster NDB 7.2), you can increase the number of data nodes in the cluster while the cluster remains in operation. See [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#), for more information.

It is also possible to increase the number of partitions for `NDB` tables by using explicit `KEY` or `LINEAR KEY` partitioning (see [Section 17.2.5, “KEY Partitioning”](#)).

### 16.1.6.6. Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in `MyISAM` tables.
- **Index prefixes.** Prefixes on indexes are not supported for `NDBCLUSTER` tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is ignored.
- **LOAD TABLE ... FROM MASTER.** `LOAD TABLE FROM MASTER` is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 16.6, “MySQL Cluster Replication”](#), for more information.

**Note**

See [Section 16.1.6.3, “Limits Relating to Transaction Handling in MySQL Cluster”](#), for more information relating to limitations on transaction handling in NDB.

### 16.1.6.7. Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.
- **Reliability of Records in range.** The `Records in range` statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See [Section 12.2.9.3, “Index Hint Syntax”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

### 16.1.6.8. Issues Exclusive to MySQL Cluster

The following are limitations specific to the NDBCLUSTER storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.** MySQL Cluster has the following limitations or restrictions with regard to binary logging:
  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  - MySQL Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
  - Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`
    - `CREATE DATABASE / CREATE SCHEMA`
    - `DROP DATABASE / DROP SCHEMA`
    - `CREATE TABLESPACE`
    - `ALTER TABLESPACE`
    - `DROP TABLESPACE`
    - `CREATE LOGFILE GROUP`
    - `ALTER LOGFILE GROUP`
    - `DROP LOGFILE GROUP`

See also [Section 16.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

### 16.1.6.9. Limitations Relating to MySQL Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces:  $2^{32}$  (4294967296)
- Maximum number of data files per tablespace:  $2^{16}$  (65536)
- The theoretical maximum number of extents per tablespace data file is  $2^{16}$  (65536); however, for practical purposes, the recommended maximum number of extents per data file is  $2^{15}$  (32768).
- Maximum data file size: The theoretical limit is 64G; however, the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), for more information.

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is prohibited altogether. (Bug #20008)

### 16.1.6.10. Limitations Relating to Multiple MySQL Cluster Nodes

**Multiple SQL nodes.** The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

**Multiple management nodes.** When using multiple management servers:

- You must give nodes explicit IDs in connect strings because automatic allocation of node IDs does not work across multiple management servers.
- When a management server starts, it first checks for any other management server in the same MySQL Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of a MySQL Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this MySQL Cluster. See [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#), for more information.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

#### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 16.3.2.8, “MySQL Cluster TCP/IP Connections”](#), for more information.

### 16.1.6.11. Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.** The `NDBCLUSTER` storage engine now supports variable-length column types for in-memory

tables.

Previously, for example, any Cluster table having one or more `VARCHAR` fields which contained only relatively small values, much more memory and disk space were required when using the `NDBCLUSTER` storage engine than would have been the case for the same table and data using the `MyISAM` engine. In other words, in the case of a `VARCHAR` column, such a column required the same amount of storage as a `CHAR` column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as `VARCHAR` and `BINARY` are comparable to those for these column types when used in `MyISAM` tables (see [Section 10.5, “Data Type Storage Requirements”](#)).

### Important

For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See [Section 16.5.11, “MySQL Cluster Disk Data Tables”](#).

- **Replication with MySQL Cluster.** It is now possible to use MySQL replication with Cluster databases. For details, see [Section 16.6, “MySQL Cluster Replication”](#).
 

**Circular Replication.** Circular replication is also supported with MySQL Cluster, beginning with MySQL 5.1.18. See [Section 16.6.10, “MySQL Cluster Replication: Multi-Master and Circular Replication”](#).
- **`auto_increment_increment` and `auto_increment_offset`.** The `auto_increment_increment` and `auto_increment_offset` server system variables are supported for MySQL Cluster Replication.
- **Backup and restore between architectures.** It is possible to perform a Cluster backup and restore between different architectures. Previously—for example—you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug #19255)
- **Multiple data nodes, multi-threaded data nodes.** MySQL Cluster NDB 7.2 supports multiple data node processes on a single host as well as multi-threaded data node processes. See [Section 16.4.3, “ndbmtcd — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.
- **Identifiers.** Formerly (in MySQL 5.0 and earlier), database names, table names and attribute names could not be as long for `NDB` tables as tables using other storage engines, because attribute names were truncated internally. In MySQL 5.1 and later, names of MySQL Cluster databases, tables, and table columns follow the same rules regarding length as they do for any other storage engine.
- **Length of `CREATE TABLE` statements.** `CREATE TABLE` statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only.* (See Bug #17813)
- **`IGNORE` and `REPLACE` functionality.** In MySQL 5.1.7 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.1.8. (See Bug #17431.)

- **`AUTO_INCREMENT` columns.** In MySQL 5.1.10 and earlier versions, the maximum number of tables having `AUTO_INCREMENT` columns—including those belonging to hidden primary keys—was 2048.

This limitation was lifted in MySQL 5.1.11.

- **Maximum number of cluster nodes.** The total maximum number of nodes in a MySQL Cluster is 255, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers. The total number of data nodes and management nodes is 63, of which up to 48 can be data nodes.

### Note

A data node cannot have a node ID greater than 49.

- **Recovery of memory from deleted rows.** Memory can be reclaimed from an `NDB` table for reuse with any `NDB` table by employing `OPTIMIZE TABLE`, subject to the following limitations:
  - Only in-memory tables are supported; the `OPTIMIZE TABLE` statement has no effect on MySQL Cluster Disk Data tables.
  - Only variable-length columns (such as those declared as `VARCHAR`, `TEXT`, or `BLOB`) are supported.

However, you can force columns defined using fixed-length data types (such as `CHAR`) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

See [Section 12.1.17, “CREATE TABLE Syntax”](#), and [Section 12.1.7, “ALTER TABLE Syntax”](#), for information on these options.

You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of 0), but not recommended. The maximum is 100000 milliseconds (that is, 100 seconds).

- **Number of tables.** The maximum number of `NDBCLUSTER` tables in a single MySQL Cluster is included in the total maximum number of `NDBCLUSTER` database objects (20320). (See [Section 16.1.6.5, “Limits Associated with Database Objects in MySQL Cluster”](#).)
- **Adding and dropping of data nodes.** In MySQL Cluster NDB 7.2 (MySQL Cluster NDB 7.0 and later), it is possible to add new data nodes to a running MySQL Cluster by performing a rolling restart, so that the cluster and the data stored in it remain available to applications.

When planning to increase the number of data nodes in the cluster online, you should be aware of and take into account the following issues:

- New data nodes can be added online to a MySQL Cluster only as part of a new node group.
- New data nodes can be added online, but cannot be dropped online. Reducing the number of data nodes requires a system restart of the cluster.
- As in previous MySQL Cluster releases, it is not possible to change online either the number of replicas (`NoOfReplicas` configuration parameter) or the number of data nodes per node group. These changes require a system restart.
- Redistribution of existing cluster data using the new data nodes is not automatic; however, this can be accomplished using simple SQL statements in the `mysql` client or other MySQL client application once the nodes have been added. During this procedure, it is not possible to perform DDL operations, although DML operations can continue as normal.

The distribution of new cluster data (that is, data stored in the cluster *after* the new nodes have been added) uses the new nodes without manual intervention.

For more information, see [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#).

- **Distribution of MySQL users and privileges.** Previously, MySQL users and privileges created on one SQL node were unique to that SQL node, due to the fact that the MySQL grant tables were restricted to using the `MyISAM` storage engine. Beginning with MySQL Cluster NDB 7.2.0, it is possible, following installation of the MySQL Cluster software and setup of the desired users and privileges on one SQL node, to convert the grant tables to use `NDB` and thus to distribute the users and privileges across all SQL nodes connected to the cluster. You can do this by loading and making use of a set of stored procedures defined in an SQL script supplied with the MySQL Cluster distribution. For more information, see [Section 16.5.13, “Distributed MySQL Privileges for MySQL Cluster”](#).

## 16.2. MySQL Cluster Installation

This section describes the basics for planning, installing, configuring, and running a MySQL Cluster. Whereas the examples in [Section 16.3, “MySQL Cluster Configuration”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading a MySQL Cluster between release versions, see [Section 16.2.7, “Upgrading and Downgrading MySQL Cluster NDB 7.2”](#).

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

**Assumptions.** The following sections make a number of assumptions regarding the cluster’s physical and network configuration. These assumptions are discussed in the next few paragraphs.

**Cluster nodes and host computers.** The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

Node	IP Address
Management node ( <a href="#">mgmd</a> )	192.168.0.10
SQL node ( <a href="#">mysqld</a> )	192.168.0.20
Data node "A" ( <a href="#">ndbd</a> )	192.168.0.30
Data node "B" ( <a href="#">ndbd</a> )	192.168.0.40

This may be made clearer by the following diagram:

**Network addressing.** In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1    ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1    localhost
127.0.0.2    ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1    localhost
127.0.0.2    ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

### Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

### Important

MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run a MySQL Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL Web site (see <http://dev.mysql.com/doc/index-other.html>). We assume that each machine has sufficient memory for running the operating system, required MySQL Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see [Chapter 2, \*Installing and Upgrading MySQL\*](#). For information about installation of MySQL Cluster on Linux and other Unix-like operating systems, see [Section 16.2.1, “Installing MySQL Cluster on Linux”](#). For information about installation of MySQL Cluster on Windows operating systems, see [Section 16.2.2, “Installing MySQL Cluster on Windows”](#).

For general information about MySQL Cluster hardware, software, and networking requirements, see [Section 16.1.3, “MySQL Cluster Hardware, Software, and Networking Requirements”](#).

## 16.2.1. Installing MySQL Cluster on Linux

This section covers installation of MySQL Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms.

MySQL Cluster NDB 7.2 is also available for Windows operating systems; for installation and setup instructions specific to Windows, see [Section 16.2.2, “Installing MySQL Cluster on Windows”](#).

Each MySQL Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmtd`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of MySQL Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the MySQL Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See [Section 16.2.3, “Initial Configuration of MySQL Cluster”](#).

### 16.2.1.1. Installing a MySQL Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest MySQL Cluster NDB 7.2 binary archive ([mysql-cluster-gpl-7.2.5-linux-i686-glibc23.tar.gz](#)) from the [MySQL Cluster downloads area](#). We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.9.3, “Installing MySQL from a Development Source Tree”](#).)

#### Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see [Section 16.2.3, “Initial Configuration of MySQL Cluster”](#)).

**Data nodes and SQL nodes.** On each of the machines designated to host data nodes or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory. Note that the actual file and directory names vary according to the MySQL Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzf mysql-cluster-gpl-7.1.20-linux-i686-glibc23.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-7.1.20-linux-i686-glibc23 /usr/local/mysql
```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 16.2.3, “Initial Configuration of MySQL Cluster”](#).)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the MySQL Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.61-ndb-7.1.20-linux-i686-glibc23.tar.gz
shell> cd mysql-5.1.61-ndb-7.1.20-linux-i686-glibc23
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In [Section 16.2.3, “Initial Configuration of MySQL Cluster”](#), we create configuration files for all of the nodes in our example MySQL Cluster.

### 16.2.1.2. Installing MySQL Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of MySQL Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The **Server** RPM (for example, `MySQL-Cluster-gpl-server-6.3.48-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-server-7.0.31-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-server-7.1.20-0.sles10.i586.rpm`), which supplies the core files needed to run a MySQL Server with NDBCLUSTER storage engine support (that is, as a MySQL Cluster SQL node).

If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the **Client** RPM (for example, `MySQL-Cluster-gpl-client-6.3.48-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-client-7.0.31-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-client-7.1.20-0.sles10.i586.rpm`).

- The **Cluster storage engine** RPM (for example, `MySQL-Cluster-gpl-storage-6.3.48-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-storage-7.0.31-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-storage-7.1.20-0.sles10.i586.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).
- The **Cluster storage engine management** RPM (for example, `MySQL-Cluster-gpl-management-6.3.48-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-management-7.0.31-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-management-7.1.20-0.sles10.i586.rpm`) which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools** RPM (for example, `MySQL-Cluster-gpl-tools-6.3.48-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-tools-7.0.31-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-tools-7.1.20-0.sles10.i586.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools** RPM (for example, `MySQL-Cluster-gpl-extra-6.3.48-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-extra-7.0.31-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-extra-7.1.20-0.sles10.i586.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see [Section 16.4, “MySQL Cluster Programs”](#).)

The MySQL Cluster version number in the RPM file names (shown here as `6.3.48`, `7.0.31`, or `7.1.20`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The `glibc` version number (if present), and architecture designation (shown here as `i586`) should be appropriate to the machine on which the RPM is to be installed.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine** RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uvh MySQL-Cluster-gpl-storage-7.1.20-0.sles10.i586.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the **Server** RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uvh MySQL-Cluster-gpl-server-7.1.20-0.sles10.i586.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in `/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

### Note

To administer the SQL node (MySQL server), you should also install the **Client** RPM, as shown here:

```
shell> rpm -Uvh MySQL-Cluster-gpl-client-7.1.20-0.sles10.i586.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL web site):

```
shell> rpm -Uvh MySQL-Cluster-gpl-management-7.1.20-0.sles10.i586.rpm
```

This installs the management server binary (`ndb_mgmd`) to the `/usr/sbin` directory.

You should also install the **NDB** management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL web site):

```
shell> rpm -Uvh MySQL-Cluster-gpl-tools-7.1.20-0.sles10.i586.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (`ndb_mgm`) to the `/usr/bin` directory.

### Note

You can also install the **Cluster storage engine extra tools** RPM, if you wish, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-gpl-extra-7.1.20-0.sles10.i586.rpm
```

You may find the extra tools useful; however the **Cluster storage engine extra tools** RPM is *not* required to install a working MySQL Cluster.

See [Section 2.5.1, “Installing MySQL from RPM Packages on Linux”](#), for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in [Section 16.2.3, “Initial Configuration of MySQL Cluster”](#).

### 16.2.1.3. Building MySQL Cluster from Source on Linux

This section provides information about compiling MySQL Cluster on Linux and other Unix-like platforms. Building MySQL Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see [Section 2.9, “Installing MySQL from Source”](#). For information about compiling MySQL Cluster on Windows platforms, see [Section 16.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”](#).

Building MySQL Cluster requires using the MySQL Cluster sources. These are available from the MySQL Cluster downloads page at <http://dev.mysql.com/downloads/cluster/>. The archived source file should have a name similar to `mysql-cluster-gpl-7.2.5.tar.gz`. You can also obtain MySQL development sources from [launchpad.net](http://launchpad.net). Attempting to build MySQL Cluster from standard MySQL Server 5.5 sources is not supported.

The `WITH_NDBCLUSTER_STORAGE_ENGINE` option for `CMake` causes the binaries for the management nodes, data nodes, and other MySQL Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option is enabled by default in the MySQL Cluster NDB 7.2 sources.

For more information about `CMake` options specific to building MySQL Cluster, see [Options for Compiling MySQL Cluster](#).

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.** When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.** The only executable required on a data node host is the data node binary `ndbd` or `ndbmtbd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling MySQL Cluster from source, no special options are required for building multi-threaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmtbd` to be built automatically; `make install` places the `ndbmtbd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.9, “Installing MySQL from Source”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.9, “Installing MySQL from Source”](#) on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In [Section 16.2.3, “Initial Configuration of MySQL Cluster”](#), we create configuration files for all of the nodes in our example MySQL Cluster.

## 16.2.2. Installing MySQL Cluster on Windows

MySQL Cluster NDB 7.2 binaries for Windows can be obtained from <http://dev.mysql.com/downloads/cluster/>. For information about installing MySQL Cluster on Windows from a binary release provided by Oracle, see [Section 16.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”](#).

It is also possible to compile and install MySQL Cluster from source on Windows using Microsoft Visual Studio. For more information, see [Section 16.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”](#).

### 16.2.2.1. Installing MySQL Cluster on Windows from a Binary Release

This section describes a basic installation of MySQL Cluster on Windows using a binary `no-install` MySQL Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see [Section 16.2, “MySQL Cluster Installation”](#)), as shown in the following table:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

As on other platforms, the MySQL Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmttd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmttd.exe`, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of MySQL Cluster node.

#### Note

As with other Windows programs, MySQL Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up a MySQL Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest MySQL Cluster Windows binary archive from <http://dev.mysql.com/downloads/cluster/>. This archive has a filename of the form `mysql-cluster-gpl-noinstall-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as `7.2.1`), and `arch` is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the MySQL Cluster NDB 7.2.1 `no-install` archive for 32-bit Windows systems is named `mysql-cluster-gpl-noinstall-7.2.1-win32.zip`.

You can run 32-bit MySQL Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit MySQL Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit MySQL Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the `no-install` archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address 192.168.0.20, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run MySQL Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-noinstall-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the MySQL Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.5`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.5\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see [Section 2.3.6, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”](#).

For a MySQL Server with MySQL Cluster support to run as part of a MySQL Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see [Section 2.3.6.2, “Creating an Option File”](#)), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

**Data nodes.** A MySQL Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndb-mtd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndb-mtd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of a MySQL Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=192.168.0.10 # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:\mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the MySQL Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting a MySQL Cluster management node is the management server program `ndb-mgmd.exe`. However, in order to administer the MySQL Cluster once it has been started, you should also install the MySQL Cluster management client program `ndb-mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb-mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the MySQL Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
# Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the plaintext file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the MySQL Cluster as a whole. At a minimum, this file must contain a section for each node in the MySQL Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:
  - The IP address or hostname of any SQL nodes
  - The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)

- The number of replicas, using the `NoOfReplicas` configuration parameter (see [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#))
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2          # Number of replicas
DataDir=C:/mysql/bin/cluster-data  # Directory for each data node's data files
                                # Forward slashes used in directory path,
                                # rather than backslashes. This is correct;
                                # see Important note in text
DataMemory=80M          # Memory allocated to data storage
IndexMemory=18M         # Memory allocated to index storage
                        # For DataMemory and IndexMemory, we have used the
                        # default values. Since the "world" database takes up
                        # only about 500KB, this should be more than enough for
                        # this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=192.168.0.10    # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs  # Directory for management node log files

[ndbd]
# Options for data node "A":
                        # (one [ndbd] section per data node)
HostName=192.168.0.30    # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=192.168.0.40    # Hostname or IP address

[mysqld]
# SQL node options:
HostName=192.168.0.20    # Hostname or IP address
```

Save this file as the plaintext file `C:\mysql\bin\config.ini`.

### Important

A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by MySQL Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of a MySQL Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs    # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in MySQL Cluster program options and configuration files on Windows.

## 16.2.2.2. Compiling and Installing MySQL Cluster from Source on Windows

Oracle provides precompiled MySQL Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile MySQL Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build MySQL Cluster, you must use the MySQL Cluster sources, which you can obtain from <http://dev.mysql.com/downloads/cluster/>.

Attempting to build MySQL Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option in addition to any other build options you wish to use before creating the Visual Studio project files. Once you have run `configure.js` with the desired options, you can create the project files and build from them in the same manner as you do when compiling the standard MySQL Server. For more information, see [Installing MySQL from Source on Windows](#).

Once the build process is complete, you can create a Zip archive containing the compiled binaries by executing `make package`. The MySQL Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see [Section 16.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”](#).

### 16.2.2.3. Initial Startup of MySQL Cluster on Windows

Once the MySQL Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the MySQL Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

- On the management node host, issue the following command from the command line to start the management node process:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO      -- NDB Cluster Management Server. mysql-5.1.61-ndb-7.1.20
2010-06-23 07:53:34 [MgmtSrvr] INFO      -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used MySQL Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of MySQL Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See [Section 16.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#), where we show how to install and run MySQL Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

#### Important

A MySQL Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

For additional information about options which can be used with `ndb_mgmd`, see [Section 16.4.4, “ndb\\_mgmd — The MySQL Cluster Management Server Daemon”](#), as well as [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

- On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO      -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see [Section 16.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#).)

- Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the MySQL Cluster management client

`ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive MySQL Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.1.61-ndb-7.1.20)
Node 3: starting (Last completed phase 3) (mysql-5.1.61-ndb-7.1.20)

Node 2: starting (Last completed phase 4) (mysql-5.1.61-ndb-7.1.20)
Node 3: starting (Last completed phase 4) (mysql-5.1.61-ndb-7.1.20)

Node 2: Started (version 7.1.20)
Node 3: Started (version 7.1.20)

ndb_mgm>
```

### Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see [Section 16.5.2, “Commands in the MySQL Cluster Management Client”](#).

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the MySQL Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the MySQL Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the MySQL Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.1.61-ndb-7.1.20, Nodegroup: 0, Master)
id=3 @192.168.0.40 (Version: 5.1.61-ndb-7.1.20, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.1.61-ndb-7.1.20)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.1.61-ndb-7.1.20)
```

You can also verify that the SQL node is connected to the MySQL Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using MySQL Cluster's `NDBCLUSTER` storage engine. See [Section 16.2.5, “MySQL Cluster Example with Tables and Data”](#), for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtdd.exe` as Windows services. For information on how to do this, see [Section 16.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#).

#### 16.2.2.4. Installing MySQL Cluster Processes as Windows Services

Once you are satisfied that MySQL Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical [Services](#) utility.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'MySQL Cluster Management Server' as 'C:\mysql\bin\ndbd.exe' "--service=ndb_mgmd"
Service successfully installed.
```

#### Important

When installing a MySQL Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `THE SYSTEM CANNOT FIND THE FILE SPECIFIED`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> NET START ndb_mgmd
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP ndb_mgmd
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'MySQL Cluster Management Server' as 'C:\mysql\bin\ndb_mgmd.exe' "--service=mgmd1"
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> NET START mgmd1
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP mgmd1
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'MySQL Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the `--remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmdl
Removing service 'mgmdl'
Service successfully removed.
```

Installation of a MySQL Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtdd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'MySQL Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP ndbd
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.

C:\> NET START 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'MySQL Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnodel
Installing service 'dnodel' as '"C:\mysql\bin\ndbd.exe" "--service=dnodel"'
Service successfully installed.

C:\> NET START dnodel
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP dnodel
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnodel
Removing service 'dnodel'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove`. For additional information, see [Section 2.3.6.7, “Starting MySQL as a Windows Service”](#).

### 16.2.3. Initial Configuration of MySQL Cluster

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a `connectstring` that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connectstrings, see [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

**Configuring the data nodes and SQL nodes.** The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

#### Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server

[mysql_cluster]
# Options for ndbd process:
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

#### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2      # Number of replicas
DataMemory=80M      # How much memory to allocate for data storage
IndexMemory=18M     # How much memory to allocate for index storage
                    # For DataMemory and IndexMemory, we have used the
                    # default values. Since the "world" database takes up
                    # only about 500KB, this should be more than enough for
                    # this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202     # This the default; however, you can use any
                    # port that is free for all the hosts in the cluster
                    # Note: It is recommended that you do not specify the port
                    # number at all and simply allow the default value to be used
                    # instead
```

```
[ndb_mgmd]
# Management process options:
hostname=192.168.0.10      # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node log files

[ndbd]
# Options for data node "A":
# (one [ndbd] section per data node)
hostname=192.168.0.30      # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

[ndbd]
# Options for data node "B":
hostname=192.168.0.40      # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20      # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

### Note

The `world` database can be downloaded from <http://dev.mysql.com/doc/>, where it can be found listed under “Examples”.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 16.2.4, “Initial Startup of MySQL Cluster”](#).

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see [Section 16.3.2, “MySQL Cluster Configuration Files”](#), and [Section 16.3, “MySQL Cluster Configuration”](#). For configuration of MySQL Cluster as relates to making backups, see [Section 16.5.3.3, “Configuration for MySQL Cluster Backups”](#).

### Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

## 16.2.4. Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See [Section 16.4.4, “ndb\\_mgmd — The MySQL Cluster Management Server Daemon”](#), for details.)

For additional options which can be used with `ndb_mgmd`, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
```

```
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.5.20-ndb-7.2.5, Nodegroup: 0, Master)
id=3 @192.168.0.40 (Version: 5.5.20-ndb-7.2.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.5.20-ndb-7.2.5)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.5.20-ndb-7.2.5)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.

### Note

The IP address shown for a given MySQL Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See [Section 16.2.5, “MySQL Cluster Example with Tables and Data”](#), for a brief discussion.

## 16.2.5. MySQL Cluster Example with Tables and Data

### Note

The information in this section applies to MySQL Cluster running on both Unix and Windows platforms.

Working with database tables and data in MySQL Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.5.20-ndb-7.2.5

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 16.5.10.2, “MySQL Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting

the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000   |
| Seoul     | 9981619    |
| São Paulo | 9968485    |
| Shanghai  | 9696300    |
| Jakarta   | 9604900    |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access [NDB](#) tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the [SELECT](#) statement just shown by using the PHP 5.X [mysqli](#) extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
  <?
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
            $row->Name, $row->Population);
?>
  </tbody>
</table>
<?
  # ...and verify the number of rows that were retrieved
  printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

## 16.2.6. Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#), for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmt` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MYSQL`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (192.168.0.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.
- On the SQL host (192.168.0.20):

```
shell> mysql_safe &
```

On Windows platforms, assuming that you have installed all MySQL Cluster processes as Windows services using the default service names (see [Section 16.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#)), you can restart the cluster as follows:

- On the management host (192.168.0.10 in our example setup), execute the following command:

```
C:\> NET START ndb_mgmd
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40), execute the following command:

```
C:\> NET START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see [Section 16.2.2.3, “Initial Startup of MySQL Cluster on Windows”](#)).
- On the SQL node host (192.168.0.20), execute the following command:

```
C:\> NET START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#).

## 16.2.7. Upgrading and Downgrading MySQL Cluster NDB 7.2

This section provides information about MySQL Cluster software and table file compatibility between different MySQL Cluster NDB 7.2 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See [Section 16.3, “MySQL Cluster Configuration”](#).

### ■ Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software.* This is especially true when planning a migration from MySQL Cluster NDB 7.1 (or earlier) to MySQL Cluster NDB 7.2, since the version of the underlying MySQL Server also changes from MySQL 5.1 to MySQL 5.5. See [Section 2.11.1, “Upgrading MySQL”](#).

**Versions supported.** The following versions of MySQL Cluster are supported for upgrades to MySQL Cluster NDB 7.2 (7.2.4 and later):

- MySQL Cluster NDB 7.1 GA releases (7.1.3 and later)
- MySQL Cluster NDB 7.0 GA releases (7.0.5 and later)
- MySQL Cluster NDB 6.3 GA releases (6.3.8 and later) that can be upgraded to MySQL Cluster NDB 7.1

For information about upgrades and downgrades in previous MySQL Cluster release series, see [Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x](#), and [Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x](#).

NDB API, ClusterJ, and other applications used with recent releases of MySQL Cluster NDB 6.3 and later should continue to work with MySQL Cluster NDB 7.2.4 and later without rewriting or recompiling.

**Upgrading `ndbd` to `ndbmt.d`.** When upgrading online from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 or later release, you should not try to upgrade the data nodes from `ndbd` to `ndbmt.d` at the same time. Instead, perform the upgrade using the new `ndbd` executable (from the MySQL Cluster distribution to which you are upgrading) to replace the one in use on the data nodes. Once the version upgrade is complete, you can perform a second (online) upgrade to replace the data node executables with `ndbmt.d` from the “new” MySQL Cluster distribution.

## 16.3. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDBCLUSTER` storage engine. This engine is also referred to simply as `NDB`, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

For more information about `--ndbcluster` and other MySQL server options specific to MySQL Cluster, see [Section 16.3.4.2, “MySQL Server Options for MySQL Cluster”](#).

The MySQL server is a part of the cluster, so it also must know how to access an MGM node to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the `NDB` storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

`NDB`, the MySQL Cluster storage engine, is available in binary distributions for Linux, Mac OS X, Solaris, and Windows. We are working to support MySQL Cluster on all operating systems supported by the MySQL Server. For information about installing MySQL Cluster, see [Section 16.2, “MySQL Cluster Installation”](#).

### 16.3.1. Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `Host-Name` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
```

```
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

By default, `ndbd` looks for the management server at `localhost` on port 1186.

### Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.5.22

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
```

```
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 5.5.20-ndb-7.2.5, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 5.5.20-ndb-7.2.5)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 5.5.20-ndb-7.2.5)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

## 16.3.2. MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

**Caching of configuration data.** In MySQL Cluster NDB 7.2, MySQL Cluster uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the `--initial` option.** In this case, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the `--reload` option.** In this case, the management server compares its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using a `--config-cache` option.** This option can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build MySQL Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at run time by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

### Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--initial`, and `--reload` options for the MySQL Cluster management server, see [Section 16.4.4, “ndb\\_mgmd — The MySQL Cluster Management Server Daemon”](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#).

## 16.3.2.1. MySQL Cluster Configuration: Basic Example

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

### Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.5)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#).)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
```

```
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional [NDB](#) variables that can be set in the `my.cnf` file, see [Section 16.3.4.3, “MySQL Cluster System Variables”](#).

The MySQL Cluster global configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (“:”) as well as the equal sign (“=”); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

### Note

In some older releases of MySQL Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

**Note**

The preceding example is intended as a minimal starting configuration for purposes of familiarization with MySQL Cluster, and is almost certain not to be sufficient for production settings. See [Section 16.3.2.2, “Recommended Starting Configuration for MySQL Cluster”](#), which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

## Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but it may be used as a convenience when setting up a large cluster. See [Section 16.3.2.4, “Defining Computers in a MySQL Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 16.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 16.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of MGM nodes, see [Section 16.3.2.5, “Defining a MySQL Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 16.3.2.8, “MySQL Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 16.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.5, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 16.3.2.10, “MySQL Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialized hardware. See [Section 16.3.2.11, “SCI Transport Connections in MySQL Cluster”](#) for detailed information about SCI interconnects.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

### 16.3.2.2. Recommended Starting Configuration for MySQL Cluster

Achieving the best performance from a MySQL Cluster depends on a number of factors including the following:

- MySQL Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the spe-

cifics of each MySQL Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the MySQL Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

**Starting `config.ini` file.** The following `config.ini` file is a recommended starting point for configuring a cluster running MySQL Cluster NDB 7.2:

```
# TCP PARAMETERS

[tcpc default]SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd1]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd2]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDBCLUSTER threads to get higher throughput.
```

```

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
# MaxNoOfTables=1024
# MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

```

**Recommended `my.cnf` options for SQL nodes.** MySQL Servers acting as MySQL Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--engine-condition-pushdown=1`

### 16.3.2.3. The MySQL Cluster Connectstring

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server's location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]
host-definition:
    host_name[:port_number]
```

*node\_id* is an integer larger than 1 which identifies a node in `config.ini`. *host\_name* is a string representing a valid Internet host name or IP address. *port\_number* is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):   "myhost1"
```

`localhost:1186` is used as the default connectstring value if none is provided. If *port\_num* is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connectstring one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connectstrings is shown here:

```
[nodeid=node_id, ]
[bind-address=host-definition, ]
host-definition[: bind-address=host-definition]
host-definition[: bind-address=host-definition]
[, ...]
```

*host-definition*:

```
host_name[:port_number]
```

If a single bind address is used in the connectstring *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connectstring causes the node to use `192.168.178.242` regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connectstring:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `192.168.178.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `192.168.178.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the

management server's `my.cnf` file.

- For backward compatibility, two other options are available, using the same syntax:
  - Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.
  - Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

#### 16.3.2.4. Defining Computers in a MySQL Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

<b>Restart Type</b>	initial, node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	
	<b>Range</b>	<code>..</code>

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

#### Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	
	<b>Range</b>	<code>..</code>

This is the computer's hostname or IP address.

#### 16.3.2.5. Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. `[mgm]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted.

#### Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

<b>Deprecated</b>	5.1.51-ndb-7.1.9	
<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	
	<b>Range</b>	1 .. 63

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of MySQL Cluster.

- `NodeId`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	
	<b>Range</b>	1 .. 63

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future MySQL Cluster release.

- `ExecuteOnComputer`

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	
	<b>Range</b>	..

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

- `PortNumber`

<b>Restart Type</b>	node
---------------------	------

	Permitted Values	
	Type	numeric
	Default	1186
	Range	0 .. 64K

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

Restart Type	system	
	Permitted Values	
	Type	string
	Default	
	Range	..

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LogDestination`

Restart Type	node	
	Permitted Values	
	Type	string
	Default	FILE:filename=ndb_nodeid_cluster.log,maxsize=1000000,maxfiles=6
	Range	..

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

### Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.
- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	1
	Range	0 .. 2

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.
- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- `ArbitrationDelay`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	0
	Range	0 .. 4G

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

Restart Type	node	
	Permitted Values	
	Type	string
	Default	.
	Range	..

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` paramet-

er for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- `HeartbeatThreadPriority`

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
{FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first out) or `RR` (round robin). The policy value is followed optionally by the priority (an integer).

- `TotalSendBufferMemory`

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters, see [Section 16.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”](#).

### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 16.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

## 16.3.2.6. Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmt` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means  $100 \times 1024 = 102400$ .) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to MySQL Cluster Disk Data tables can be found later in this section.

All of these parameters also apply to `ndbmt` (the multi-threaded version of `ndbd`). An additional data node configuration parameter `MaxNoOfExecutionThreads` applies to `ndbmt` only, and has no effect when used with `ndbd`. For more information, see [Section 16.4.3, “ndbmt — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the

node is started or in the configuration file.

- `Id`

<b>Deprecated</b>	5.1.51-ndb-7.1.9	
<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	
	<b>Range</b>	<code>1 .. 48</code>

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes. Although the older `Id` is still supported for backward compatibility, it is now deprecated, and generates a warning when used. `Id` is also subject to removal in a future MySQL Cluster release.

- `NodeId`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	
	<b>Range</b>	<code>1 .. 48</code>

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes. Although `Id` continues to be supported for backward compatibility, it is now deprecated, generates a warning when used, and is subject to removal in a future version of MySQL Cluster.

- `ExecuteOnComputer`

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	
	<b>Range</b>	<code>..</code>

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

- `HostName`

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>localhost</code>
	<b>Range</b>	<code>..</code>

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `ServerPort`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	
	Range	1 .. 64K

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

### Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`; see [Section 16.3.2.5, “Defining a MySQL Cluster Management Server”](#)) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (0).

- `NodeGroup`

Restart Type	initial, system	
	Permitted Values	
	Type	numeric
	Default	
	Range	0 .. 65536

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running MySQL Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 16.5.12.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”](#).

- `NoOfReplicas`

Restart Type	initial, system	
	Permitted Values	
	Type	numeric
	Default	None
	Range	1 .. 4

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	None
	<b>Range</b>	1 .. 4
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	2
	<b>Range</b>	1 .. 4
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	2
	<b>Range</b>	1 .. 4

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2, which is the recommended setting in most common usage scenarios.

The maximum possible value is 4; *currently, only the values 1 and 2 are actually supported.*

### Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since  $2/3$  and  $2/4$  both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

<b>Restart Type</b>	initial, node	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	.
	<b>Range</b>	..

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

<b>Restart Type</b>	initial, node
---------------------	---------------

	Permitted Values	
	Type	<code>string</code>
	Default	<code>DataDir</code>
	Range	<code>..</code>

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

### Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

Restart Type	initial, node	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>FileSystemPath</code>
	Range	<code>..</code>

This parameter specifies the directory in which backups are placed.

### Important

The string `'/BACKUP'` is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

## Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory`

Restart Type	node	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>80M</code>
	Range	<code>1M .. 1024G</code>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate datapages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

Currently, MySQL Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `TABLE IS FULL` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory`. This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force NDB to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient. In MySQL Cluster 7.2.3 and later, you can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts. (Bug #13436216)

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

Restart Type	node	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>18M</code>
	Range	<code>1M .. 1T</code>

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

- `StringMemory`

<b>Restart Type</b>	system	
	<b>Permitted Values (<math>\geq 5.5</math>)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	25
	<b>Range</b>	0 .. 4G

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 `OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER: PERMANENT ERROR: SCHEMA ERROR`, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be

acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Beginning with MySQL Cluster NDB 7.2.3, a proportion (5% by default) of data node resources including [DataMemory](#) and [IndexMemory](#) is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the [MinFreePct](#) data node configuration parameter (default 5) introduced in the same version of MySQL Cluster.

<b>Version Introduced</b>	5.5.17-ndb-7.2.3	
<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	5
	<b>Range</b>	0 .. 100
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	5
	<b>Range</b>	0 .. 100
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	5
	<b>Range</b>	0 .. 100

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few [\[ndbd\]](#) parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. [MaxNoOfConcurrentTransactions](#) sets the number of parallel transactions possible in a node. [MaxNoOfConcurrentOperations](#) sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially [MaxNoOfConcurrentOperations](#)) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

[MaxDMLOperationsPerTransaction](#) sets the maximum number of DML operations that can be performed in a given transaction.

- [MaxNoOfConcurrentTransactions](#)

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	4096
	<b>Range</b>	32 .. 4G

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for this parameter is

```
MaxNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of cluster SQL nodes
```

Suppose that there are 4 SQL nodes using the cluster. A single join involving 5 tables requires 6 transaction records; if there are 5 such joins in a transaction, then  $5 * 6 = 30$  transaction records are required for this transaction, per MySQL server, or  $30 * 4 = 120$  transaction records total.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

Changing the value of `MaxNoOfConcurrentTransactions` requires a complete shutdown and restart of the cluster.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	32K
	Range	32 .. 4G

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ .

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	UNDEFINED
	Range	32 .. 4G

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- [MaxDMLOperationsPerTransaction](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	4294967295
	Range	32 .. 4294967295
	Permitted Values	
	Type	numeric
	Default	4294967295
	Range	32 .. 4294967295

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set [MaxDMLOperationsPerTransaction](#) to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of [\[ndbd\]](#) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	8K
	Range	0 .. 4G

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- [MaxNoOfFiredTriggers](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	4000
	Range	0 .. 4G

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `TransactionBufferMemory`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	1M
	Range	1K .. 4G

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZAT-TRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains  $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.** There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to  $10000 \times 128$  bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to  $10000 \times 16$  bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `MaxNoOfConcurrentScans`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	256
	Range	2 .. 500

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- `MaxNoOfLocalScans`

Restart Type	node
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> UNDEFINED
	<b>Range</b> 32 .. 4G

Specifies the number of local scan records if many scans are not fully parallelized. In MySQL Cluster NDB 7.2.0 and later, when the number of local scan records is not provided, it is calculated as 4 times the product of [MaxNoOfConcurrentScans](#) and the number of data nodes in the system. (Previously, it was calculated as the product of [MaxNoOfConcurrentScans](#) and the number of data nodes.) The minimum value is 32.

- [BatchSizePerLocalScan](#)

Restart Type	node
	<b>Permitted Values (&gt;= 5.5)</b>
	<b>Type</b> numeric
	<b>Default</b> 256
	<b>Range</b> 1 .. 992

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

The default value is 64; this value has a strong connection to the [BatchSize](#) defined in the SQL nodes.

- [LongMessageBuffer](#)

Restart Type	node
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 1M
	<b>Range</b> 512K .. 4G
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 4M
	<b>Range</b> 512K .. 4G

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 4MB.

This parameter seldom needs to be changed from the default.

- [MaxParallelScansPerFragment](#)

Restart Type	node
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 32
	<b>Range</b> 1 .. 1G
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 32
	<b>Range</b> 1 .. 1G

	Permitted Values	
	Type	numeric
	Default	256
	Range	1 .. 1G

It is possible to configure the maximum number of parallel scans (**TUP** scans and **TUX** scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

Beginning with MySQL Cluster NDB 7.2.0, the default value for this parameter was increased from 32 to 256.

## Memory Allocation

### MaxAllocate

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives **OUT OF MEMORY** errors, but it is evident by examining the cluster logs or the output of **DUMP 1000** (see **DUMP 1000**) that all available memory has not yet been used, you can increase the value of this parameter (or **MaxNoOfTables**, or both) to cause NDB to make sufficient memory available.

**Logging and checkpointing.** The following **[ndbd]** parameters control log and checkpoint behavior.

- **NoOfFragmentLogFiles**

Restart Type	initial, node	
	Permitted Values	
	Type	numeric
	Default	16
	Range	3 .. 4G

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until the required number of local checkpoints has been completed since that log record was inserted. (In MySQL Cluster NDB 7.2, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the **FragmentLogFileSize** parameter. In scenarios requiring a great many updates, the value for **NoOfFragmentLogFiles** may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (**Out of log file space temporarily**). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

### Important

This parameter cannot be changed “on the fly”; you must restart the node using **--initial**. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using **--initial** when starting each data node).

- **FragmentLogFileSize**

Restart Type	initial, node
--------------	---------------

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	16M
	<b>Range</b>	4M .. 1G

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when MySQL Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for [NoOfFragmentLogFiles](#).

- [InitFragmentLogFiles](#)

<b>Restart Type</b>	initial, node	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	
	<b>Range</b>	..

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. [InitFragmentLogFiles](#) takes either of two values:

- [SPARSE](#). Fragment log files are created sparsely. This is the default value.
- [FULL](#). Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting [InitFragmentLogFiles=FULL](#) may help eliminate I/O errors on writes to the REDO log.

- [MaxNoOfOpenFiles](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	20 .. 4G

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- [InitialNoOfOpenFiles](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	27
	<b>Range</b>	20 .. 4G

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [MaxNoOfSavedMessages](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	25
	<b>Range</b>	0 .. 4G

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

- [MaxLCPStartDelay](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 600
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 600

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- [MaxNoOfAttributes](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1000
	<b>Range</b>	32 .. 4G

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older MySQL Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (*greatest\_number\_of\_attributes*) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be  $6 * \text{greatest\_number\_of\_attributes} = 600$ .

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	128
	Range	8 .. 20320

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older MySQL Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

#### Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- `MaxNoOfOrderedIndexes`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	128
	Range	0 .. 4G

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

### Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- `MaxNoOfUniqueHashIndexes`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	64
	Range	0 .. 4G

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

### Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- `MaxNoOfTriggers`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	768
	Range	0 .. 4G

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

This parameter is deprecated in MySQL Cluster 5.5 and later; you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

- [MaxNoOfSubscriptions](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	0
	Range	0 .. 4G
	Permitted Values	
	Type	numeric
	Default	0
	Range	0 .. 4G

Each [NDB](#) table in a MySQL Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for [MaxNoOfSubscriptions](#) is 0, which is treated as equal to [MaxNoOfTables](#). Each subscription consumes 108 bytes.

- [MaxNoOfSubscribers](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	0
	Range	0 .. 4G
	Permitted Values	
	Type	numeric
	Default	0
	Range	0 .. 4G

This parameter is of interest only when using MySQL Cluster Replication. The default value is 0, which is treated as  $2 * \text{MaxNoOfTables}$ ; that is, there is one subscription per [NDB](#) table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three MySQL Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set [MaxNoOfSubscribers](#) equal to  $3 * \text{MaxNoOfTables}$ .

For more information, see [Section 16.6, “MySQL Cluster Replication”](#).

- [MaxNoOfConcurrentSubOperations](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	256
	Range	0 .. 4G

	Permitted Values	
	Type	numeric
	Default	256
	Range	0 .. 4G

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `LockPagesInMainMemory`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	0
	Range	0 .. 2

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values `0`, `1`, or `2`, which act as shown in the following list:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (`LockPagesInMainMemory` uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and <http://linux.die.net/man/2/mlock>).

### Note

In older MySQL Cluster releases, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated. In MySQL Cluster NDB 7.2, using `true` or `false` as the value of this parameter causes an error.

- `StopOnError`

Restart Type	node	
	Permitted Values	
	Type	boolean
	Default	true
	Range	..

This parameter specifies whether an `ndbd` process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- `CrashOnCorruptedTuple`

<b>Version Introduced</b>	5.5.16-ndb-7.2.1	
<b>Restart Type</b>		
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

When this parameter is enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. In MySQL Cluster NDB 7.2.1 and later, it is enabled by default. This is a change from MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, where it was disabled by default.

- `Diskless`

<b>Restart Type</b>	initial, system	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 1</code>

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

### Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `ODirect`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 1</code>
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 1</code>
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 1</code>

Enabling this parameter causes **NDB** to attempt using **O\_DIRECT** writes for LCP, backups, and redo logs, often lowering **kswapd** and CPU usage. When using MySQL Cluster on Linux, enable **ODirect** if you are using a 2.6 or later kernel.

**ODirect** is disabled by default.

- **RestartOnErrorInsert**

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	2
	Range	0 .. 4

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- **CompressedBackup**

Restart Type	node	
	Permitted Values	
	Type	boolean
	Default	false
	Range	..

Setting this parameter to **1** causes backup files to be compressed. The compression used is equivalent to **gzip --fast**, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the **[ndbd default]** section of the **config.ini** file).

### Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is **0** (disabled).

- **CompressedLCP**

Restart Type	node	
	Permitted Values	
	Type	boolean
	Default	false
	Range	..

Setting this parameter to **1** causes local checkpoint files to be compressed. The compression used is equivalent to **gzip --fast**, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the **[ndbd default]** section of the **config.ini** file).

### Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is **0** (disabled).

## Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	6000
	Range	70 .. 4G

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	6000
	Range	70 .. 4G

This is similar to the `TimeBetweenWatchDogCheck` parameter, except that `TimeBetweenWatchDogCheckInitial` controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- `StartPartialTimeout`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	30000
	Range	0 .. 4G

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- `StartPartitionedTimeout`

Restart Type	node
--------------	------

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	60000
	<b>Range</b>	0 .. 4G

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4G

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- `StartNoNodeGroupTimeout`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	15000
	<b>Range</b>	0 .. 4294967039

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#), for more information.

- `HeartbeatIntervalDbDb`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1500
	<b>Range</b>	10 .. 4G

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

In MySQL Cluster NDB 7.2.0 and later, the default heartbeat interval is 5000 milliseconds (5 seconds). (Previously, the default was 1500 milliseconds [1.5 seconds]). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also [Network communication and latency](#).

- [HeartbeatIntervalDbApi](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	1500
	Range	100 .. 4G

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see [Network communication and latency](#).

- [HeartbeatOrder](#)

Restart Type	system	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	0
	Range	0 .. 65535

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers [host1](#) and [host2](#), and that these data nodes make up 2 node groups, as shown in the following table:

	<a href="#">host1</a>	<a href="#">host2</a>
Node Group 0:	Node A	Node B
Node Group 1:	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Node	HeartbeatOrder
A	10
B	20
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running MySQL Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

Restart Type	node	
	Permitted Values	
	Type	string
	Default	1500
	Range	0 .. 4G

This parameter enables connection checking between data nodes. A data node that fails to respond within an interval of `ConnectCheckIntervalDelay` seconds is considered suspect, and is considered dead after two such intervals.

The default value for this parameter is 0; this is a change from MySQL Cluster NDB 7.1.

- `TimeBetweenLocalCheckpoints`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	20
	Range	0 .. 31

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	2000
	<b>Range</b>	10 .. 32000

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenEpochs`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	100
	<b>Range</b>	0 .. 32000

This parameter defines the interval between synchronisation epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

`TimeBetweenEpochs` is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication.

- `TimeBetweenEpochsTimeout`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	4000
	<b>Range</b>	0 .. 256000

This parameter defines a timeout for synchronization epochs for MySQL Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. In MySQL Cluster NDB 7.2.0 and later, the default value is 0; in other words, the timeout is disabled. This represents a change from previous versions of MySQL Cluster, in which the default value was 4000 milliseconds (4 seconds).

`TimeBetweenEpochsTimeout` is part of the implementation of “micro-GCPs”, which can be used to improve the performance

of MySQL Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP save takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- [MaxBufferedEpochs](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	100
	Range	0 .. 100000

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the [NDB](#) client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- [TimeBetweenInactiveTransactionAbortCheck](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	1000
	Range	1000 .. 4G

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	4G
	Range	0 .. 4G

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	1200
	Range	50 .. 4G

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- [DiskSyncSize](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	4M
	Range	32K .. 4G

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

### Note

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- [DiskCheckpointSpeed](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	10M
	Range	1M .. 4G

The amount of data, in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

The default value is 10M (10 megabytes per second).

- [DiskCheckpointSpeedInRestart](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	100M
	Range	1M .. 4G

The amount of data, in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

- [NoOfDiskPagesToDiskAfterRestartTUP](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	40
	Range	1 .. 4G

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting [NoOfDiskPagesToDiskAfterRestartTUP](#) to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. (See the entry for [IndexMemory](#) for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with [NoOfFragmentLogFiles](#), [DataMemory](#), and [IndexMemory](#).

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see [Configuring MySQL Cluster Parameters for Local Checkpoints](#).

The default value is 40 (3.2MB of data pages per second).

#### Note

This parameter is deprecated. Use [DiskCheckpointSpeedInRestart](#) and [DiskSyncSize](#) instead.

- [NoOfDiskPagesToDiskAfterRestartACC](#)

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	20
	Range	1 .. 4G

This parameter uses the same units as [NoOfDiskPagesToDiskAfterRestartTUP](#) and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

#### Note

This parameter is deprecated. Use [DiskCheckpointSpeedInRestart](#) and [DiskSyncSize](#) instead.

- [NoOfDiskPagesToDiskDuringRestartTUP](#) (DEPRECATED)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	40
	Range	1 .. 4G

This parameter is used in a fashion similar to [NoOfDiskPagesToDiskAfterRestartTUP](#) and [NoOfDiskPagesToDiskAfterRestartACC](#), only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

### Note

This parameter is deprecated. Use [DiskCheckpointSpeedInRestart](#) and [DiskSyncSize](#) instead.

- [NoOfDiskPagesToDiskDuringRestartACC](#) (DEPRECATED)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	20
	Range	1 .. 4G

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with [NoOfDiskPagesToDiskAfterRestartTUP](#) and [NoOfDiskPagesToDiskAfterRestartACC](#), values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

### Note

This parameter is deprecated. Use [DiskCheckpointSpeedInRestart](#) and [DiskSyncSize](#) instead.

- [ArbitrationTimeout](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	3000
	Range	10 .. 4G

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

In MySQL Cluster NDB 7.2.0 and later, the default value is 7500 milliseconds (7.5 seconds). Previously, this was 3000 milliseconds (3 seconds).

- [Arbitration](#)

Restart Type	node	
	Permitted Values	
	Type	enumeration
	Default	Default
	Valid Values	Default Disabled WaitExternal

The `Arbitration` parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.
- **Disabled.** Setting `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplish the same task as setting `ArbitrationRank` to 0 on all management and API nodes. When `Arbitration` is set in this way, any `ArbitrationRank` settings are ignored.
- **WaitExternal.** The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

### Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

**Buffering and logging.** Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine's file system abstraction layer.

- `UndoIndexBuffer`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	2M
	Range	1M .. 4G

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- `UndoDataBuffer`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	16M
	Range	1M .. 4G

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`DATA UNDO BUFFERS OVERLOADED`).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- `RedoBuffer`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	8M
	Range	1M .. 4G

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

`RedoBuffer` sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO LOG BUFFERS OVERLOADED`). For this reason, you should exercise care if you attempt to decrease the value of `RedoBuffer` as part of an online change in the cluster's configuration.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>
	<b>Range</b>	<code>0 .. 15</code>

The reporting level for events generated during startup of the process.

The default level is 1.

- `LogLevelShutdown`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 15</code>

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- `LogLevelStatistic`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 15</code>

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- `LogLevelCheckpoint`

<b>Restart Type</b>	initial, node
---------------------	---------------

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 15

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 15

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 15

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 15

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

<b>Restart Type</b>	node	
---------------------	------	--

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 15

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 15

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4G

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the [DataMemory](#) and [IndexMemory](#), respectively, set in the [config.ini](#) file. For example, if [DataMemory](#) is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

[MemReportFrequency](#) is not a required parameter. If used, it can be set for all cluster data nodes in the [\[ndbd default\]](#) section of [config.ini](#), and can also be set or overridden for individual data nodes in the corresponding [\[ndbd\]](#) sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 16.5.5.2, “MySQL Cluster Log Events”](#).

- [StartupStatusReportFrequency](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric

When a data node is started with the [--initial](#), it initializes the redo log file during Start Phase 4 (see [Section 16.5.1, “Summary of MySQL Cluster Start Phases”](#)). When very large values are set for [NoOfFragmentLogFiles](#), [FragmentLogFileSize](#), or

both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Debugging Parameters.** In MySQL Cluster NDB 7.2, it is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value; currently, 0 (default - no logging) and 1 (logging enabled) are the only supported values.

**Backup parameters.** The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	2M
	Range	0 .. 4G

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.

The default value for this parameter is 16MB.

- `BackupLogBufferSize`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	2M
	Range	0 .. 4G

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 16.5.3.3, “Configuration for MySQL Cluster Backups”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- [BackupMemory](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	4M
	Range	0 .. 4G

This parameter is simply the sum of [BackupDataBufferSize](#) and [BackupLogBufferSize](#).

The default value of this parameter in MySQL Cluster NDB 7.2 is 16MB + 16MB = 32MB.

### Important

If [BackupDataBufferSize](#) and [BackupLogBufferSize](#) taken together exceed the default value for [BackupMemory](#), then this parameter must be set explicitly in the `config.ini` file to their sum.

- [BackupReportFrequency](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	0
	Range	0 .. 4G

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

- [BackupWriteSize](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	32K
	Range	2K .. 4G

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- [BackupMaxWriteSize](#)

Restart Type	node	
	Permitted Values (>= 5.5)	
	Type	<a href="#">numeric</a>
	Default	1M
	Range	2K .. 4G

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

### Important

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

## MySQL Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

### Note

To make use of these parameters, the data node process must be run as system root.

- `LockExecuteThreadToCPU`

Restart Type	node	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>64K</code>
	Range	<code>0 .. 64K</code>

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmt`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter; beginning with in MySQL Cluster NDB 7.2.5, you can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`

Restart Type	node	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>64K</code>
	Range	<code>0 .. 64K</code>

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). In MySQL Cluster NDB 7.2, there is no default value.

- [RealtimeScheduler](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	false
	<b>Range</b>	..

Setting this parameter to 1 enables real-time scheduling of `NDBCLUSTER` threads.

The default is 0 (scheduling disabled).

- [SchedulerExecutionTimer](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	50
	<b>Range</b>	0 .. 11000

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50  $\mu$ sec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- [SchedulerSpinTimer](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 500

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- [BuildIndexThreads](#)

<b>Restart Type</b>		
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 128

This parameter determines the number of threads to create when rebuilding indexes during a system or node start. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (which is also the default value) disables multi-threaded building of ordered indexes. The maximum allowed value is 128.

This parameter is supported when using `ndbd` or `ndbmtd`.

You can enable multi-threaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- `TwoPassInitialNodeRestartCopy`

Multi-threaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

- `ThreadConfig`

<b>Version Introduced</b>	5.5.17-ndb-7.2.3		
<b>Restart Type</b>	node		
	<b>Permitted Values</b>		
	<b>Type</b>	<code>string</code>	
	<b>Default</b>	<code>[none]</code>	

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
entry := type={param[,param[,...]]}
type := ldm | main | recv | rep | io
param := count=number | cpubind=cpu_list
```

The curly braces (`{...}`) surrounding the list of parameters is required, even if there is only one parameter in the list.

The `type` attribute represents an NDB thread type. Permitted values and their associated thread types are described in the following list:

- `ldm`: Local query handler (`DBLQH` kernel block)
- `main`: Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks)
- `recv`: NDB kernel virtual machine (`CMVMI` kernel block)
- `rep`: `SUMA` kernel block
- `io`: File system and other miscellaneous operations

A `param` (parameter) specifies the number of threads of the given type (`count`), the CPUs to which the threads of the given type are to be bound (`cpubind`), or both.

Examples:

```
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={count=2,cpubind=3,4}
```

## Numa

<b>Restart Type</b>	node
---------------------	------

	Permitted Values	
	Type (linux)	boolean
	Default	0

NDB is extremely sensitive to Non-Uniform Memory Access settings and multi-CPU systems due to timeouts that it can cause. Due to this fact, and because most MySQL Cluster users do not employ `numactl`, support for NUMA is ignored by default by `ndbd` when running on a Linux system. If your Linux system provides NUMA support and you wish for data node memory to be subject to NUMA control, you can set this parameter equal to 0.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is installed.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferMemory`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	64M
	Range	4M .. 1T

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always uses  $N * 32$  KB memory where  $N$  is some nonnegative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See [Section 16.5.9.4, “The ndbinfo diskpagebuffer Table”](#), for more information.

- `SharedGlobalMemory`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	20M
	Range	0 .. 64T

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, `UNDO` files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `INITIAL_SIZE` and `UNDO_BUFFER_SIZE` options used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for these options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

As of MySQL Cluster NDB 7.2.0, the default value is `128M`. (Previously, this was `20M`.)

- `DiskIOThreadPool`

Restart Type	node
--------------	------

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	8
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	2
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	2
	<b>Range</b>	0 .. 4G

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

Currently, this parameter applies to Disk Data I/O threads only, but we plan in the future to make the number of such threads configurable for in-memory data as well.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.
- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

In MySQL Cluster NDB 7.2, the default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place MySQL Cluster Disk Data files in specific directories without the need for using symbolic links.
  - `FileSystemPathDD`

Restart Type	initial, node	
	Permitted Values	
	Type	file name
	Default	FileSystemPath
	Range	..

If this parameter is specified, then MySQL Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

<b>Restart Type</b>	initial, node	
	<b>Permitted Values</b>	
	<b>Type</b>	file name
	<b>Default</b>	FileSystemPathDD
	<b>Range</b>	..

If this parameter is specified, then MySQL Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

<b>Restart Type</b>	initial, node	
	<b>Permitted Values</b>	
	<b>Type</b>	file name
	<b>Default</b>	FileSystemPathDD
	<b>Range</b>	..

If this parameter is specified, then MySQL Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `CREATE LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 16.5.11.1, “MySQL Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- `InitialLogFileGroup`

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	[see documentation]
	<b>Range</b>	..

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
file-specification-list:
    file-specification[; file-specification[; ...]]
```

```
file-specification:
  filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each *file-specification* corresponds to an undo log file, and at least one must be specified in the *file-specification-list*. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are taken from the global memory pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter; if this parameter is set too low and the values set in `InitialLogFileGroup` for the logfile group's initial size or undo buffer size are too high, the cluster may fail to create the default log file group when starting, or fail to start altogether.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of a MySQL Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

Restart Type	system	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	[see documentation]
	<b>Range</b>	<code>..</code>

This parameter can be used to specify a MySQL Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The *file-specification-list* uses the same syntax as shown with the `InitialLogFileGroup` parameter, the only difference being that each *file-specification* used with `InitialTablespace` corresponds to a data file. At least one must be specified in the *file-specification-list*. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogFileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of a MySQL Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD UNDOFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating MySQL Cluster Disk Data tables thereafter.

**Disk Data and GCP STOP errors.** Errors encountered when using Disk Data tables such as `NODE NODEID KILLED THIS NODE BECAUSE GCP STOP WAS DETECTED` (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see [Section 16.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”](#).

- `ExtraSendBufferMemory`

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

This parameter was added in MySQL Cluster NDB 7.2.5. (Bug #11760629, Bug #53053)

- `TotalSendBufferMemory`

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

Prior to MySQL Cluster NDB 7.2.5, this parameter did not work correctly with `ndbmtid`. (Bug #13633845)

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039.

- `ReservedSendBufferMemory`

This parameter is present in `NDBCLUSTER` source code beginning with MySQL Cluster NDB 6.4.0. However, it is not currently enabled.

As of MySQL Cluster NDB 7.2.5, this parameter is deprecated, and is subject to removal in a future release of MySQL Cluster (Bug #11760629, Bug #53053).

For more detailed information about the behavior and use of `TotalSendBufferMemory` and about configuring send buffer memory parameters in MySQL Cluster, see [Section 16.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”](#).

See also [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#).

**Redo log over-commit handling.** It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- `RedoOverCommitCounter`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	3
	Range	0 .. 4G

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

`RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit.

- `RedoOverCommitLimit`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	20
	Range	0 .. 4G

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts. This parameter was added in MySQL Cluster NDB 7.1.10.

**Controlling restart attempts.** It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

`MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are described in more detail in the next few paragraphs.

`StartFailRetryDelay`

Restart Type	node
--------------	------

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4G

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

#### Note

This parameter is ignored unless `StartOnError` is equal to 0.

#### MaxStartFailRetries

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	3
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	3
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	3
	<b>Range</b>	0 .. 4G
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	3
	<b>Range</b>	0 .. 4G

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

#### Note

This parameter is ignored unless `StopOnError` is equal to 0.

### 16.3.2.7. Defining SQL and Other API Nodes in a MySQL Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

#### Note

For a discussion of MySQL server options for MySQL Cluster, see [Section 16.3.4.2, “MySQL Server Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 16.3.4.3, “MySQL Cluster System Variables”](#).

- `Id`

<b>Deprecated</b>	5.1.51-ndb-7.1.9	
<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	
	<b>Range</b>	1 .. 63

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

#### Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying API nodes. (`Id` continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- `NodeId`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	
	<b>Range</b>	1 .. 63

The `NodeId` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

#### Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes in MySQL Cluster NDB 7.2 and later. Previously, `Id` was used for this purpose and this continues to be supported for backward compatibility. `Id` is now deprecated and generates a warning when used; it is subject to removal in a future release of MySQL Cluster.

- [ExecuteOnComputer](#)

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">string</a>
	<b>Default</b>	
	<b>Range</b>	<a href="#">..</a>

This refers to the [Id](#) set for one of the computers (hosts) defined in a [\[computer\]](#) section of the configuration file.

- [HostName](#)

<b>Restart Type</b>	system	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">string</a>
	<b>Default</b>	
	<b>Range</b>	<a href="#">..</a>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a host-name, either this parameter or [ExecuteOnComputer](#) is required.

If no [HostName](#) or [ExecuteOnComputer](#) is specified in a given [\[mysql\]](#) or [\[api\]](#) section of the [config.ini](#) file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where [localhost](#) is assumed for [HostName](#) unless otherwise specified.*

- [ArbitrationRank](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	<a href="#">0</a>
	<b>Range</b>	<a href="#">0 .. 2</a>

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting [ArbitrationRank](#) to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the [Arbitration](#) parameter in the [\[ndbd default\]](#) section of the [config.ini](#) global configuration file.

- [ArbitrationDelay](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	<a href="#">0</a>
	<b>Range</b>	<a href="#">0 .. 4G</a>

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	<a href="#">32K</a>
	Range	<a href="#">1024 .. 1M</a>

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 16KB in MySQL Cluster NDB 7.2.1 and later. (Previously, the default was 32K.)

- [BatchSize](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	<a href="#">64</a>
	Range	<a href="#">1 .. 992</a>

This parameter is measured in number of records and is by default set to 256 (MySQL Cluster NDB 7.2.1 and later; previously, the default was 64). The maximum size is 992.

- [HeartbeatThreadPriority](#)

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
policy:
{FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first in) or [RR](#) (round robin). This followed optionally by the priority (an integer).

- [MaxScanBatchSize](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">numeric</a>
	Default	<a href="#">256K</a>
	Range	<a href="#">32K .. 16M</a>

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- [TotalSendBufferMemory](#)

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	256K
	<b>Range</b>	0 .. 4G

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters in MySQL Cluster, see [Section 16.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”](#).

- `AutoReconnect`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	false
	<b>Range</b>	false .. true

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

#### Note

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()`, and `Ndb_cluster_connection::get_auto_reconnect()`.

- `DefaultOperationRedoProblemAction`

<b>Restart Type</b>		
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	
	<b>Valid Values</b>	ABORT QUEUE

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- `ABORT`: Any pending operations from aborted transactions are also aborted.
- `QUEUE`: Pending operations from transactions that were aborted are queued up to be re-tried.

You can obtain some information from a MySQL server running as a Cluster SQL node using `SHOW STATUS` in the `mysql` client, as

shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 192.168.0.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)
```

For information about these Cluster system status variables, see [Section 5.1.5, “Server Status Variables”](#).

### Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

## 16.3.2.8. MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

### Note

For an exception to this rule, see [Section 16.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

### Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `NodeId1`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	
	Range	..

- `NodeId2`

Restart Type	node
--------------	------

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	
	<b>Range</b>	..

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file. These are the same unique `NodeId` (or `Id`) values for each of these nodes as described in [Section 16.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `HostName1`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	
	<b>Range</b>	..

- `HostName2`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	
	<b>Range</b>	..

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- `OverloadLimit`

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 16.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”](#), for more information.

In some older releases, the effective value of this parameter was limited by the size of `SendBufferMemory`; in MySQL Cluster NDB 7.2, the actual value for `OverloadLimit` (up to the stated maximum of 4G) is used instead.

- `SendBufferMemory`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	256K
	<b>Range</b>	64K .. 4G

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in MySQL Cluster, see

### Section 16.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”.

The default size of the send buffer in MySQL Cluster NDB 7.2 is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- `SendSignalId`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>false (debug builds: true)</code>
	<b>Range</b>	<code>..</code>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>false</code>
	<b>Range</b>	<code>..</code>

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `PortNumber` (*OBSOLETE*)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used; use the `ServerPort` data node configuration parameter for this purpose instead.

- `ReceiveBufferMemory`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>64K</code>
	<b>Range</b>	<code>16K .. 4G</code>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

## 16.3.2.9. MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 16.3.2.10. MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

#### Important

*SHM functionality is considered experimental only.* It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- `NodeId1`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	
	Range	..

#### `NodeId2`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	
	Range	..

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `HostName1`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	
	<b>Range</b>	<code>..</code>

- `HostName2`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	
	<b>Range</b>	<code>..</code>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- `ShmKey`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	
	<b>Range</b>	<code>0 .. 4G</code>

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- `ShmSize`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1M</code>
	<b>Range</b>	<code>64K .. 4G</code>

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- `SendSignalId`

<b>Restart Type</b>	node	
---------------------	------	--

	Permitted Values	
	Type	boolean
	Default	false
	Range	..

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

Restart Type	node	
	Permitted Values	
	Type	boolean
	Default	true
	Range	..

This parameter is a boolean (`Y/N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- `SigNum`

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	
	Range	0 .. 4G

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of `SigNum` is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

### 16.3.2.11. SCI Transport Connections in MySQL Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The `path` should point to a directory that contains at a minimum `lib` and `include` directories containing SISI libraries and header files. (See [Section 16.3.5, “Using High-Speed Interconnects with MySQL Cluster”](#) for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- `NodeId1`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	
	<b>Range</b>	..

- `NodeId2`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	
	<b>Range</b>	..

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `Host1SciId0`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	
	<b>Range</b>	0 .. 4G

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- `Host1SciId1`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4G

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `Host2SciId0`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	
	<b>Range</b>	0 .. 4G

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `Host2SciId1`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 4G</code>

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `HostName1`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	
	<b>Range</b>	<code>..</code>

- `HostName2`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	
	<b>Range</b>	<code>..</code>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- `SharedBufferSize`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>10M</code>
	<b>Range</b>	<code>64K .. 4G</code>

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- `SendLimit`

<b>Restart Type</b>	node	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>8K</code>
	<b>Range</b>	<code>128 .. 32K</code>

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- [SendSignalId](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">boolean</a>
	Default	<a href="#">true</a>
	Range	<a href="#">..</a>

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to [Y](#), message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in [-debug](#) builds.

- [Checksum](#)

Restart Type	node	
	Permitted Values	
	Type	<a href="#">boolean</a>
	Default	<a href="#">false</a>
	Range	<a href="#">..</a>

This parameter is a boolean value, and is disabled by default. When [Checksum](#) is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

### 16.3.2.12. Configuring MySQL Cluster Send Buffer Parameters

Formerly, the NDB kernel employed a send buffer whose size was fixed at 2MB for each node in the cluster, this buffer being allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

This problem was eventually solved (in MySQL Cluster NDB 7.0) by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can be accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of MySQL Cluster nodes—that is, it can be set in the [\[ndbd\]](#), [\[mgm\]](#), and [\[api\]](#) (or [\[mysql\]](#)) sections of the [config.ini](#) file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Transporter	Maximum Send Buffer Size (bytes)
TCP	<a href="#">SendBufferMemory</a> (default = 2M)
SCI	<a href="#">SendLimit</a> (default = 8K) plus 16K
SHM	20K

This enables existing configurations to function in close to the same way as they did with MySQL Cluster NDB 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`SEND BUFFERS OVERLOADED IN NDB KERNEL`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.
- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

### 16.3.3. Overview of MySQL Cluster Configuration Parameters

The next four sections provide summary tables of MySQL Cluster configuration parameters used in the `config.ini` file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types (`ndbd`, `ndb_mgmd`, and `mysqld`), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

These tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter.

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

#### Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

#### Note

`4294967039` often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RN1L` and is equal to `0xFFFFFFFF`, or  $2^{32} - 2^8 - 1$ .

#### 16.3.3.1. MySQL Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 16.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

These parameters also apply to `ndbmt`, the multi-threaded version of `ndbd`. For more information, see [Section 16.4.3, “ndbmt —](#)

The MySQL Cluster Data Node Daemon (Multi-Threaded)”.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 16.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

MySQL Cluster NDB 7.2 supports the addition of new data node groups online, to a running cluster. For more information, see [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#).

**Table 16.1. Data Node Configuration Parameters**

Name	Type/Units	Default	Min Value	Max Value	Restart Type

### 16.3.3.2. MySQL Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 16.3.2.5, “Defining a MySQL Cluster Management Server”](#).

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 16.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

**Table 16.2. Management Node Configuration Parameters**

Name	Type/Units	Default	Min Value	Max Value	Restart Type
<a href="#">ArbitrationDelay</a>	milliseconds			4G	N
<a href="#">ArbitrationRank</a>	0-2	1		2	N
<a href="#">DataDir</a>	path	.			N
<a href="#">ExecuteOnComputer</a>	name				S
HeartbeatThreadPriority		none			
<a href="#">HostName</a>	name or IP address				S
<a href="#">Id</a>	unsigned		1	63	N
<a href="#">LogDestination</a>	{CONSOLE SYSLOG FILE}	FILE:filename=ndb_nodeid_cluster.log,maxsize=1000000,maxfiles=6			N
MaxNoOfSavedEvents	unsigned	100		4G	N
<a href="#">NodeId</a>	unsigned		1	63	N
<a href="#">PortNumber</a>	unsigned	1186		64K	N
PortNumberStats	unsigned			64K	N
wan		false			N

### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 16.3.2.5, “Defining a MySQL Cluster Management Server”](#), for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 16.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

## 16.3.3.3. MySQL Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 16.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

### Note

For a discussion of MySQL server options for MySQL Cluster, see [Section 16.3.4.2, “MySQL Server Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 16.3.4.3, “MySQL Cluster System Variables”](#).

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 16.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

**Table 16.3. SQL Node/API Node Configuration Parameters**

Name	Type/Units	Default	Min Value	Max Value	Restart Type
<a href="#">ArbitrationDelay</a>	milliseconds			4G	N

Name	Type/Units	Default	Min Value	Max Value	Restart Type
<a href="#">ArbitrationRank</a>	0-2			2	N
<a href="#">AutoReconnect</a>		false	false	true	N
<a href="#">BatchByteSize</a>	bytes	32K	1024	1M	N
<a href="#">BatchSize</a>	records	64	1	992	N
<a href="#">ConnectionMap</a>					N
<a href="#">DefaultOperationRedo-ProblemAction</a>					
<a href="#">ExecuteOnComputer</a>	name				S
<a href="#">HeartbeatThreadPriority</a>		none			
<a href="#">HostName</a>	name or IP address				S
<a href="#">Id</a>	unsigned		1	63	N
<a href="#">MaxScanBatchSize</a>	bytes	256K	32K	16M	N
<a href="#">NodeId</a>	unsigned		1	63	N
<a href="#">TotalSendBufferMemory</a>	bytes	256K		4G	N
<a href="#">wan</a>		false			N

### Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

## 16.3.3.4. Other MySQL Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see [Section 16.3.2.8, “MySQL Cluster TCP/IP Connections”](#), [Section 16.3.2.10, “MySQL Cluster Shared-Memory Connections”](#), or [Section 16.3.2.11, “SCI Transport Connections in MySQL Cluster”](#), as appropriate.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 16.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

## 16.3.4. MySQL Server Options and Variables for MySQL Cluster

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see [Section 5.1, “The MySQL Server”](#).

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 16.3, “MySQL Cluster Configuration”](#).

### 16.3.4.1. MySQL Cluster `mysqld` Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in a MySQL Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 5.1.1, “Server Option and Variable Reference”](#).

**Table 16.8. MySQL Server Option and Variable Reference for MySQL Cluster**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">Handler_discover</a>				Yes	Both	No

### 16.3.4.2. MySQL Server Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see [Section 5.1.2, “Server Command Options”](#).

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#). For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see [Section 16.4, “MySQL Cluster Programs”](#).

- `--ndb-batch-size=#`

<b>Command-Line Format</b>	<code>--ndb-batch-size</code>	
<b>Option-File Format</b>	<code>ndb-batch-size</code>	
<b>Variable Name</b>	<code>ndb_batch_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>32768</code>
	<b>Range</b>	<code>0 .. 31536000</code>

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

<b>Command-Line Format</b>	<code>--ndb-cluster-connection-pool</code>	
<b>Option-File Format</b>	<code>ndb-cluster-connection-pool</code>	
<b>Variable Name</b>	<code>ndb_cluster_connection_pool</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>
	<b>Range</b>	<code>1 .. 63</code>

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

#### Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connectstring when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connectstring when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

### Note

In some older releases of MySQL Cluster prior to MySQL Cluster NDB 7.2, there was also a separate status variable corresponding to this option; however, the status variable was removed as redundant as of these versions. (Bug #60119)

- `--ndb-blob-read-batch-bytes=bytes`

<b>Command-Line Format</b>	<code>--ndb-blob-read-batch-bytes</code>	
<b>Option-File Format</b>	<code>ndb-blob-read-batch-bytes</code>	
<b>Variable Name</b>	<code>ndb_blob_read_batch_bytes</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>65535</code>
	<b>Range</b>	<code>0 .. 4294967295</code>

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in MySQL Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65535. Setting it to 0 has the effect of disabling `BLOB` read batching.

### Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-blob-write-batch-bytes=bytes`

<b>Command-Line Format</b>	<code>--ndb-blob-write-batch-bytes</code>	
<b>Option-File Format</b>	<code>ndb-blob-write-batch-bytes</code>	
<b>Variable Name</b>	<code>ndb_blob_write_batch_bytes</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>65535</code>
	<b>Range</b>	<code>0 .. 4294967295</code>

This option can be used to set the size (in bytes) for batching of `BLOB` data writes in MySQL Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be written within the current transaction, any pending `BLOB` write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65535. Setting it to 0 has the effect of disabling `BLOB` write batching.

### Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobWriteBytes()` and

■ `getMaxPendingBlobWriteBytes()` methods.

- `--ndb-connectstring=connect_string`

<b>Command-Line Format</b>	<code>--ndb-connectstring</code>	
<b>Option-File Format</b>	<code>ndb-connectstring</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#), for syntax.

- `--ndb-deferred-constraints=[TRUE|FALSE]`

<b>Command-Line Format</b>	<code>--ndb-deferred-constraints</code>	
<b>Option-File Format</b>	<code>ndb-deferred-constraints</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_deferred_constraints</code>	
<b>Variable Name</b>	<code>ndb-deferred-constraints</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>false</code>
	<b>Range</b>	<code>false .. true</code>

Controls whether or not constraint checks are deferred, where these are supported. `OFF` is the default.

This option was added in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.17.

- `--ndb-distribution=[KEYHASH|LINHASH]`

<b>Command-Line Format</b>	<code>--ndb-distribution={KEYHASH LINHASH}</code>	
<b>Option-File Format</b>	<code>ndb-distribution</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_distribution</code>	
<b>Variable Name</b>	<code>ndb-distribution</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>KEYHASH</code>
	<b>Valid Values</b>	<code>LINHASH</code> <code>KEYHASH</code>

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `--ndb-mgmd-host=host[:port]`

<b>Command-Line Format</b>	<code>--ndb-mgmd-host=host[:port]</code>
<b>Option-File Format</b>	<code>ndb-mgmd-host</code>

	Permitted Values	
	Type	string
	Default	localhost:1186

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndbcluster`

Command-Line Format	<code>--ndbcluster</code>		
Option-File Format	<code>ndbcluster</code>		
Option Sets Variable	Yes, <code>have_ndbcluster</code>		
Disabled by	<code>skip-ndbcluster</code>		
	Permitted Values		
	Type	<code>boolean</code>	
	Default	<code>FALSE</code>	

The `NDBCLUSTER` storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the `NDB-CLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-log-apply-status`

Command-Line Format	--ndb-log-apply-status		
Option-File Format	ndb-log-apply-status		
Option Sets Variable	Yes, ndb_log_apply_status		
Variable Name	ndb_log_apply_status		
Variable Scope	Global		
Dynamic Variable	No		
	Permitted Values		
	Type	boolean	
	Default	OFF	

Causes a slave `mysqld` to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current `mysqld`.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating MySQL Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-transaction-id`

<b>Version Introduced</b>	5.5.15-ndb-7.2.1
<b>Command-Line Format</b>	<code>--ndb-log-transaction-id[={0 1}]</code>

<b>Option-File Format</b>	ndb-log-transaction-id	
<b>Option Sets Variable</b>	Yes, ndb_log_transaction_id	
<b>Variable Name</b>	ndb_log_transaction_id	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	OFF

Causes a slave `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, `--log-bin-use-v1-row-events` must be set to `FALSE` in order to use this option.

This option is available beginning with MySQL Cluster NDB 7.2.1 (and is not supported in mainline MySQL Server 5.5). It is required to enable MySQL Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function introduced in the same MySQL Cluster release.

The default value is `FALSE`.

For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `--ndb-nodeid=#`

<b>Command-Line Format</b>	<code>--ndb-nodeid=#</code>	
<b>Option-File Format</b>	ndb-nodeid	
<b>Variable Name</b>	Ndb_cluster_node_id	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Range</b>	1 .. 255

Set this MySQL server's node ID in a MySQL Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connectstring.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDB-CLUSTER STATUS`.

For more information about node IDs for MySQL Cluster SQL nodes, see [Section 16.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `--ndb-log-empty-epochs=[0|1]`

<b>Command-Line Format</b>	<code>--ndb-log-empty-epochs</code>	
<b>Option-File Format</b>	ndb-log-empty-epochs	
<b>Variable Name</b>	ndb_log_empty_epochs	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	

	Permitted Values	
	Type	boolean
	Default	OFF

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--server-id-bits=#`

Command-Line Format	<code>--server-id-bits=#</code>	
Option-File Format	<code>server-id-bits</code>	
Option Sets Variable	Yes, <code>server_id_bits</code>	
Variable Name	<code>server_id_bits</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	numeric
	Default	32
	Range	7 .. 32

This option indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (MySQL Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of `server_id` in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of `server_id` must be less than  $2^{\text{server\_id\_bits}}$ ; otherwise, `mysqld` refuses to start.

This system variable is supported only by MySQL Cluster. It is not supported in the standard MySQL 5.5 Server.

- `--skip-ndbcluster`

Command-Line Format	<code>--skip-ndbcluster</code>
Option-File Format	<code>skip-ndbcluster</code>

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 16.3.1, “Quick Test Setup of MySQL Cluster”, for an example.

- `--ndb-wait-connected=seconds`

Command-Line Format	<code>--ndb-wait-connected=#</code>
---------------------	-------------------------------------

<b>Option-File Format</b>	ndb-wait-connected	
<b>Variable Name</b>	ndb-wait-connected	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 31536000
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 31536000
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	30
	<b>Range</b>	0 .. 31536000
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	30
	<b>Range</b>	0 .. 31536000

This option sets the period of time that the MySQL server waits for connections to MySQL Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 30.

- `--ndb-wait-setup=seconds`

<b>Command-Line Format</b>	--ndb-wait-setup=#	
<b>Option-File Format</b>	ndb-wait-setup	
<b>Variable Name</b>	ndb-wait-setup	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	15
	<b>Range</b>	0 .. 31536000
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	15
	<b>Range</b>	0 .. 31536000
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	30
	<b>Range</b>	0 .. 31536000

	Permitted Values	
	Type	numeric
	Default	30
	Range	0 .. 31536000

This variable shows the period of time that the MySQL server waits for the [NDB](#) storage engine to complete setup before timing out and treating [NDB](#) as unavailable. The time is specified in seconds. The default value is [30](#).

- `--ndb_optimization_delay=milliseconds`

Variable Name	ndb_optimization_delay	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	10
	Range	0 .. 100000

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on [NDB](#) tables. The default is 15.

### 16.3.4.3. MySQL Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to MySQL Cluster and the [NDB](#) storage engine. For system variables not specific to MySQL Cluster, see [Section 5.1.3, “Server System Variables”](#). For general information on using system variables, see [Section 5.1.4, “Using System Variables”](#).

- `have_ndbcluster`

Variable Name	have_ndbcluster	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	boolean

`YES` if `mysqld` supports `NDBCLUSTER` tables. `DISABLED` if `--skip-ndbcluster` is used.

This variable is deprecated and is removed in MySQL 5.6. Use `SHOW ENGINES` instead.

- `multi_range_count`

Command-Line Format	<code>--multi_range_count=#</code>
Option-File Format	<code>multi_range_count</code>
Option Sets Variable	Yes, <code>multi_range_count</code>
Variable Name	<code>multi_range_count</code>
Variable Scope	Global, Session
Dynamic Variable	Yes

	Permitted Values	
	Type	numeric
	Default	256
	Range	1 .. 4294967295

The maximum number of ranges to send to a table handler at once during range selects. The default value is 256. Sending multiple ranges to a handler at once can improve the performance of certain selects dramatically. This is especially true for the [NDB-CLUSTER](#) table handler, which needs to send the range requests to all nodes. Sending a batch of those requests at once reduces communication costs significantly.

This variable is deprecated in MySQL 5.1, and is no longer supported in MySQL 5.5, in which arbitrarily long lists of ranges can be processed.

- [ndb\\_autoincrement\\_prefetch\\_sz](#)

Command-Line Format	--ndb_autoincrement_prefetch_sz	
Option-File Format	ndb_autoincrement_prefetch_sz	
Option Sets Variable	Yes, <a href="#">ndb_autoincrement_prefetch_sz</a>	
Variable Name	<a href="#">ndb_autoincrement_prefetch_sz</a>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	1
	Range	1 .. 256

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization—makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. Default value: 32. Minimum value: 1.

This variable affects only the number of [AUTO\\_INCREMENT](#) IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time. The default value for [ndb\\_autoincrement\\_prefetch\\_sz](#) is 1, to increase the speed of statements inserting single rows.

The maximum value for [ndb\\_autoincrement\\_prefetch\\_sz](#) is 65536.

- [ndb\\_cache\\_check\\_time](#)

Command-Line Format	--ndb_cache_check_time	
Option-File Format	<a href="#">ndb_cache_check_time</a>	
Option Sets Variable	Yes, <a href="#">ndb_cache_check_time</a>	
Variable Name	<a href="#">ndb_cache_check_time</a>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	0

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- `ndb_deferred_constraints`

<b>Command-Line Format</b>	<code>--ndb-deferred-constraints</code>	
<b>Option-File Format</b>	<code>ndb_deferred_constraints</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_deferred_constraints</code>	
<b>Variable Name</b>	<code>ndb_deferred_constraints</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>false</code>
	<b>Range</b>	<code>false .. true</code>

Controls whether or not constraint checks are deferred, where these are supported. `OFF` is the default.

- `ndb_distribution`

<b>Command-Line Format</b>	<code>--ndb-distribution={KEYHASH LINHASH}</code>	
<b>Option-File Format</b>	<code>ndb_distribution</code>	
<b>Variable Name</b>	<code>ndb_distribution={KEYHASH LINHASH}</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>KEYHASH</code>
	<b>Valid Values</b>	<code>LINHASH</code> <code>KEYHASH</code>

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `ndb_extra_logging`

<b>Command-Line Format</b>	<code>ndb_extra_logging=#</code>	
<b>Option-File Format</b>	<code>ndb_extra_logging</code>	
<b>Variable Name</b>	<code>ndb_extra_logging</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>

This variable can be used to enable recording in the MySQL error log of information specific to the `NDB` storage engine. It is normally of interest only when debugging `NDB` storage engine code.

The default value is 0, which means that the only **NDB**-specific information written to the MySQL error log relates to transaction handling. If the value is greater than 0 but less than 10, **NDB** table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other **NDB** errors and information. If the value is set to 10 or more, information about **NDB** internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log.

- `ndb_force_send`

<b>Command-Line Format</b>	<code>--ndb-force-send</code>	
<b>Option-File Format</b>	<code>ndb_force_send</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_force_send</code>	
<b>Variable Name</b>	<code>ndb_force_send</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>TRUE</code>

Forces sending of buffers to **NDB** immediately, without waiting for other threads. Defaults to `ON`.

- `ndb_index_stat_cache_entries`

<b>Command-Line Format</b>	<code>--ndb_index_stat_cache_entries</code>	
<b>Option-File Format</b>	<code>ndb_index_stat_cache_entries</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>32</code>
	<b>Range</b>	<code>0 .. 4294967295</code>

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: `32`.

### Note

If `ndb_index_stat_enable` is `OFF`, then setting this variable has no effect.

- `ndb_index_stat_enable`

<b>Command-Line Format</b>	<code>--ndb_index_stat_enable</code>	
<b>Option-File Format</b>	<code>ndb_index_stat_enable</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

Use **NDB** index statistics in query optimization. Defaults to `ON`.

- `ndb_index_stat_update_freq`

<b>Command-Line Format</b>	<code>--ndb_index_stat_update_freq</code>	
<b>Option-File Format</b>	<code>ndb_index_stat_update_freq</code>	

	Permitted Values	
	Type	numeric
	Default	20
	Range	0 .. 4294967295

How often to query data nodes instead of the statistics cache. For example, a value of 20 (the default) means to direct every 20<sup>th</sup> query to the data nodes.

### Note

If `ndb_index_stat_cache_entries` is 0, then setting this variable has no effect; in this case, every query is sent directly to the data nodes.

- `ndb_join_pushdown`

Variable Name	ndb_join_pushdown		
Variable Scope	Global		
Dynamic Variable	No		
	Permitted Values		
	Type	boolean	
	Default	TRUE	

Added in MySQL Cluster NDB 7.2.0, this variable controls whether joins on NDB tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of NDB by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type.

This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.
3. Explicit locking is not supported; however, the NDB storage engine's characteristic implicit row-based locking is enforced.

This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

Outer joined child tables can only be pushed using `eq_ref`.

If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by [`LINEAR`] `HASH`, `LIST`, or `RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```

mysql> EXPLAIN
->      SELECT e.first_name, e.last_name, t.title, d.dept_name
->      FROM employees e
->      JOIN dept_emp de ON e.emp_no=de.emp_no
->      JOIN departments d ON d.dept_no=de.dept_no
->      JOIN titles t ON e.emp_no=t.emp_no\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: d
      type: ALL
possible_keys: PRIMARY
      key: NULL
      key_len: NULL
      ref: NULL
      rows: 9
      Extra: Parent of 4 pushed join@1
***** 2. row *****
      id: 1
      select_type: SIMPLE
      table: de
      type: ref
possible_keys: PRIMARY,emp_no,dept_no
      key: dept_no
      key_len: 4
      ref: employees.d.dept_no
      rows: 5305
      Extra: Child of 'd' in pushed join@1
***** 3. row *****
      id: 1
      select_type: SIMPLE
      table: e
      type: eq_ref
possible_keys: PRIMARY
      key: PRIMARY
      key_len: 4
      ref: employees.de.emp_no
      rows: 1
      Extra: Child of 'de' in pushed join@1
***** 4. row *****
      id: 1
      select_type: SIMPLE
      table: t
      type: ref
possible_keys: PRIMARY,emp_no
      key: emp_no
      key_len: 4
      ref: employees.de.emp_no
      rows: 19
      Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)

```

### Note

If inner joined child tables are joined by [ref](#), and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables [Ndb\\_pushed\\_queries\\_defined](#), [Ndb\\_pushed\\_queries\\_dropped](#), [Ndb\\_pushed\\_queries\\_executed](#), and [Ndb\\_pushed\\_reads](#) (all introduced in MySQL Cluster NDB 7.2.0).
2. The counters in the [ndbinfo.counters](#) table that belong to the [DBSPJ](#) kernel block. (These counters and the [DBSPJ](#) block were also introduced in MySQL Cluster NDB 7.2.0). See [Section 16.5.9.3, “The ndbinfo counters Table”](#), for information about these counters. See also [The DBSPJ Block](#), in the *MySQL Cluster API Developer Guide*.

- [ndb\\_log\\_apply\\_status](#)

<b>Command-Line Format</b>	<a href="#">--ndb-log-apply-status</a>
<b>Option-File Format</b>	<a href="#">ndb-log-apply-status</a>
<b>Option Sets Variable</b>	Yes, <a href="#">ndb_log_apply_status</a>
<b>Variable Name</b>	<a href="#">ndb_log_apply_status</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

	Permitted Values	
	Type	boolean
	Default	OFF

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

<b>Command-Line Format</b>	<code>--ndb-log-bin={1 0}</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_log_bin</code>	
<b>Variable Name</b>	<code>ndb_log_bin</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

Causes updates to NDB tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. `ndb_log_bin` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- `ndb_log_binlog_index`

<b>Command-Line Format</b>	<code>--ndb-log-binlog-index={1 0}</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_log_binlog_index</code>	
<b>Variable Name</b>	<code>ndb_log_binlog_index</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- `ndb_log_transaction_id`

<b>Version Introduced</b>	5.5.15-ndb-7.2.1	
<b>Variable Name</b>	<code>ndb_log_transaction_id</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	Permitted Values	
	Type	boolean
	Default	OFF

This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” MySQL Cluster Replication with `NDB$EPOCH_TRANS( )` conflict detection). To change the setting, use the `–`

`--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is available in MySQL Cluster NDB 7.2.1 and later. It is not supported in mainline MySQL Server 5.5.

For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `ndb_optimized_node_selection`

Command-Line Format	- - ndb- optim- ized- node- selec- tion	4.1.9-5.1.2 2-ndb-6.33	
	--ndb-optimized-node-selection=#		
Option-File Format	ndb_optimized_node_selection		
	Permitted Values		
	Type	boolean	
	Default	ON	
	Permitted Values		
	Type	numeric	
	Default	3	
	Range	0 .. 3	

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- 0: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
  - 1: Proximity to the SQL node is used to determine the transaction coordinator.
  - 2: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
  - 3: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)
- `ndb_report_thresh_binlog_epoch_slip`

<b>Command-Line Format</b>	<code>--ndb_report_thresh_binlog_epoch_slip</code>
<b>Option-File Format</b>	<code>ndb_report_thresh_binlog_epoch_slip</code>

	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	3
	<b>Range</b>	0 .. 256

This is a threshold on the number of epochs to be behind before reporting binary log status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message will be sent to the cluster log.

- `ndb_report_thresh_binlog_mem_usage`

<b>Command-Line Format</b>	<code>--ndb_report_thresh_binlog_mem_usage</code>	
<b>Option-File Format</b>	<code>ndb_report_thresh_binlog_mem_usage</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	0 .. 10

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message will be sent to the cluster log.

- `slave_allow_batching`

<b>Command-Line Format</b>	<code>--slave-allow-batching</code>	
<b>Option-File Format</b>	<code>slave_allow_batching</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_allow_batching</code>	
<b>Variable Name</b>	<code>slave_allow_batching</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	off

Whether or not batched updates are enabled on MySQL Cluster replication slaves.

This variable is available beginning with MySQL Cluster NDB 6.2.3. Currently, it is available for `mysqld` only as supplied with MySQL Cluster or built from the MySQL Cluster sources. For more information, see [Section 16.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#).

- `ndb_table_no_logging`

<b>Variable Name</b>	<code>ndb_table_no_logging</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables `A` and `B` are not checkpointed; `A` was created with `ENGINE NDB` and `B` was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables `C` and `D` are logged; `C` was altered to use `NDB` and `D` was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to `1` or `ON` does *not* cause table `C` or `D` to be checkpointed.

### Note

`ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

Variable Name	<code>ndb_table_temporary</code>	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

When set to `ON` or `1`, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

### Note

Setting this variable currently has no effect in MySQL Cluster NDB 7.0 and later. This is a known issue; see [BUG#34036](#).

- `ndb_use_copying_alter_table`

Variable Name	<code>ndb_use_copying_alter_table</code>
Variable Scope	Global, Session
Dynamic Variable	No

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

- `ndb_use_exact_count`

Variable Name	<code>ndb_use_exact_count</code>
Variable Scope	Global, Session
Dynamic Variable	Yes

	Permitted Values	
	Type	boolean
	Default	ON

Forces NDB to use a count of records during `SELECT COUNT( *)` query planning to speed up this type of query. The default value is `ON`. For faster queries overall, disable this feature by setting the value of `ndb_use_exact_count` to `OFF`.

- `ndb_use_transactions`

<b>Command-Line Format</b>	<code>--ndb_use_transactions</code>	
<b>Option-File Format</b>	<code>ndb_use_transactions</code>	
<b>Variable Name</b>	<code>ndb_use_transactions</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

You can disable NDB transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

- `transaction_allow_batching`

<b>Variable Name</b>	<code>transaction_allow_batching</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	Yes	
	Permitted Values	
	Type	boolean
	Default	FALSE

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

### Important

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for MySQL Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

<b>Variable Name</b>	<code>ndbinfo_database</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	ndbinfo

Shows the name used for the `NDB` information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--ndbinfo-database=name`, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- `ndbinfo_max_bytes`

<b>Command-Line Format</b>	<code>--ndbinfo-max-bytes=#</code>	
<b>Option Sets Variable</b>	Yes, <code>ndbinfo_max_bytes</code>	
<b>Variable Name</b>	<code>ndbinfo_max_bytes</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0

Used in testing and debugging only.

- `ndbinfo_max_rows`

<b>Command-Line Format</b>	<code>--ndbinfo-max-rows=#</code>	
<b>Option Sets Variable</b>	Yes, <code>ndbinfo_max_rows</code>	
<b>Variable Name</b>	<code>ndbinfo_max_rows</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10

Used in testing and debugging only.

- `ndbinfo_show_hidden`

<b>Command-Line Format</b>	<code>--ndbinfo-show-hidden={0 1}</code>	
<b>Option Sets Variable</b>	Yes, <code>ndbinfo_show_hidden</code>	
<b>Variable Name</b>	<code>ndbinfo_show_hidden</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	no

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- `ndbinfo_table_prefix`

<b>Command-Line Format</b>	<code>--ndbinfo-table-prefix=name</code>	
<b>Option Sets Variable</b>	Yes, <code>ndbinfo_table_prefix</code>	
<b>Variable Name</b>	<code>ndbinfo_table_prefix</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>ndb\$</code>

The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is “`ndb$`”. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- `ndbinfo_version`

<b>Variable Name</b>	<code>ndbinfo_version</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Shows the version of the `ndbinfo` engine in use; read-only.

- `ndb_log_empty_epochs`

<b>Command-Line Format</b>	<code>--ndb-log-empty-epochs</code>	
<b>Option-File Format</b>	<code>ndb_log_empty_epochs</code>	
<b>Variable Name</b>	<code>ndb_log_empty_epochs</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- `server_id_bits`

<b>Command-Line Format</b>	<code>--server-id-bits=#</code>	
<b>Option-File Format</b>	<code>server-id-bits</code>	
<b>Option Sets Variable</b>	Yes, <code>server_id_bits</code>	
<b>Variable Name</b>	<code>server_id_bits</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	

	Permitted Values	
	Type	numeric
	Default	32
	Range	7 .. 32

The effective value of `server_id` if the server was started with the `--server-id-bits` option set to a nondefault value.

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`, `mysqld` refuses to start.

This system variable is supported only by MySQL Cluster. `server_id_bits` is not supported by the standard MySQL Server.

#### 16.3.4.4. MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the `NDB` storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see [Section 5.1.5, “Server Status Variables”](#).

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_wait_exec_complete_count_session`

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_slave`

The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_session`

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_slave`

The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_session`

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_slave`

The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_session`

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_slave`

Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in

scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count`

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count_session`

Amount of data (in bytes) sent to the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count_slave`

Amount of data (in bytes) sent to the data nodes by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count`

Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_session`

Amount of data (in bytes) received from the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_slave`

Amount of data (in bytes) received from the data nodes by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count`

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_session`

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_slave`

The number of transactions started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count`

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_session`

The number of transactions committed in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_slave`

The number of transactions committed by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count`

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_session`

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_slave`

The number of transactions aborted by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count`

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_session`

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_slave`

The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count`

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_session`

The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_slave`

The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_session`

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_slave`

The number of operations by this slave based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_session`

The number of table scans that have been started in this client session, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_slave`

The number of table scans that have been started by this slave, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count`

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_session`

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_slave`

The number of range scans that have been started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count`

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_session`

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_slave`

The number of scans by this slave that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count`

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_session`

The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_slave`

The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count`

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_slave`

The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_slave`

The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count_injector`

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count`

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count_injector`

The number of events received, other than row change events, by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count`

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count_injector`

The number of bytes of events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count`

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 16.5.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_cluster_node_id`

If the server is acting as a MySQL Cluster node, then the value of this variable is its node ID in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.

- `Ndb_config_from_port`

If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- `Ndb_conflict_fn_max`

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_old`

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch`

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch_trans`

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_row_conflict_count`

Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

Currently, the only transactional conflict detection function supported by MySQL Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_row_reject_count`

Used in MySQL Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_reject_count`

Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_detect_iter_count`

Used in MySQL Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_conflict_commit_count`

Used in MySQL Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

- `Ndb_execute_count`

Provides the number of round trips to the `NDB` kernel made by operations.

- `Ndb_number_of_data_nodes`

If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- `Ndb_pushed_queries_defined`

The total number of joins pushed down to the `NDB` kernel for distributed handling on the data nodes. Note that joins tested using `EXPLAIN` that can be pushed down contribute to this number. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_queries_dropped`

The number of joins that were pushed down to the `NDB` kernel but that could not be handled there. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_queries_executed`

The number of joins successfully pushed down to `NDB` and executed there. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_reads`

The number of rows returned to `mysqld` from the `NDB` kernel by joins that were pushed down. Note that executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pruned_scan_count`

This variable holds a count of the number of scans executed by `NDBCLUSTER` since the MySQL Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

- `Ndb_scan_count`

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the MySQL Cluster was last started.

### 16.3.5. Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 16.3.2.8, “MySQL Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See [Section 16.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 16.3.2.10, “MySQL Cluster Shared-Memory Connections”](#).

#### Note

SHM is considered experimental only, and is not officially supported.

- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, [Section 16.3.2.11, “SCI Transport Connections in MySQL Cluster”](#).

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by [Dolphin Interconnect Solutions](#).

#### 16.3.5.1. Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from [Dolphin Interconnect Solutions](#). SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, Windows, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the [Dolphin SCI online documentation](#).

#### 16.3.5.2. MySQL Cluster Interconnects and Performance

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.
- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests also benefit from batching.
- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the

`ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index.** When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See [Section 16.3.5.1, “Configuring MySQL Cluster to use SCI Sockets”](#), for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

## 16.4. MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node processes (`ndbd`, `ndbmt`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Other NDB utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are covered later in this chapter.

The final portion of this chapter contains tables of options used, respectively, with `mysqld` and with the various MySQL Cluster programs.

### 16.4.1. MySQL Server Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDBCLUSTER` storage engine, as it is in the precompiled binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `configure` with one of the options to enable `NDBCLUSTER` storage engine support:

- `--with-plugins=ndbcluster`
- `--with-plugins=max`
- `--with-plugins=max-no-innodb`

(`--with-ndbcluster` also works to enable `NDBCLUSTER` support, but is deprecated and so produces a `configure` warning as of MySQL 5.1.9.)

For information about other MySQL server options and variables relevant to MySQL Cluster in addition to those discussed in this section, see [Section 16.3.4, “MySQL Server Options and Variables for MySQL Cluster”](#).

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#), for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
  Id: 1
  User: system user
  Host:
  db:
  Command: Daemon
  Time: 1
  State: Waiting for event from ndbcluster
  Info: NULL
```

### Important

To participate in a MySQL Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server *without* the `--ndbcluster` option.

## 16.4.2. `ndbd` — The MySQL Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the MySQL Cluster data node program `ndbd`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.9. `ndbd` Command Line Options**

Format	Description	Introduc- tion	Deprecated	Removed
<code>--bind-address=name</code>	Local bind address			
<code>--daemon</code>	Start <code>ndbd</code> as daemon (default); override with <code>--nodaemon</code>			
<code>--foreground</code>	Run <code>ndbd</code> in foreground, provided for debugging purposes (implies <code>--nodaemon</code> )			
<code>--initial</code>	Perform initial start of <code>ndbd</code> , including cleaning the file system. Consult the documentation before using this option			
<code>--initial-start</code>	Perform partial initial start (requires <code>--nowait-nodes</code> )			
<code>--install[=name]</code>	Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.			
<code>--nodaemon</code>	Do not start <code>ndbd</code> as daemon; provided for testing purposes			
<code>--nostart</code>	Don't start <code>ndbd</code> immediately; <code>ndbd</code> waits for command to start from <code>ndb_mgmd</code>			
<code>--nowait-nodes=list</code>	Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires <code>--ndb-nodeid</code> to be used.			
<code>--remove[=name]</code>	Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.			

**Note**

All of these options also apply to the multi-threaded version of this program (`ndbmtbd`) and you may substitute “`ndbmtbd`” for “`ndbd`” wherever the latter occurs in this section.

For options common to all `NDBCLUSTER` programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

- `--bind-address`

Command-Line Format	<code>--bind-address=name</code>	
	Permitted Values	
	Type	<code>string</code>
	Default	

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

- `--daemon, -d`

Command-Line Format	<code>--daemon</code>	
	<code>-d</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>TRUE</code>

Instructs `ndbd` or `ndbmtbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmtbd` on Windows platforms.

- `--nodaemon`

<b>Command-Line Format</b>	<code>--nodaemon</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE
	<b>Permitted Values</b>	
	<b>Type</b> (windows)	boolean
	<b>Default</b>	TRUE

Prevents `ndbd` or `ndbmt` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for re-directing output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmt` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--foreground`

<b>Command-Line Format</b>	<code>--foreground</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Causes `ndbd` or `ndbmt` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--initial`

<b>Command-Line Format</b>	<code>--initial</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the MySQL Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

### Important

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- MySQL Cluster Disk Data files (see [Section 16.5.11](#), “MySQL Cluster Disk Data Tables”).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in a MySQL Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

Command-Line Format	<code>--initial-start</code>	
	Permitted Values	
	Type	boolean
	Default	FALSE

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

### Important

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

Command-Line Format	<code>--nowait-nodes=list</code>	
	Permitted Values	
	Type	string
	Default	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

- `--nostart, -n`

Command-Line Format	<code>--nostart</code>
	<code>-n</code>

	Permitted Values	
	Type	boolean
	Default	FALSE

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 16.5.2, “Commands in the MySQL Cluster Management Client”](#)).

- `--install[=name]`

Command-Line Format	<code>--install[=name]</code>	
	Permitted Values	
	Type (windows)	string
	Default	ndbd

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--remove[=name]`

Command-Line Format	<code>--remove[=name]</code>	
	Permitted Values	
	Type (windows)	string
	Default	ndbd

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is the node's unique identifier. Note that `node_id` represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
```

```

Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***

```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [ndbd Error Messages](#).

### Important

*The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.*

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#), for additional information about this issue. [Section 16.4.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.5 in a production setting. See [Section 16.1.6, “Known Limitations of MySQL Cluster”](#).

## 16.4.3. `ndbmt` — The MySQL Cluster Data Node Daemon (Multi-Threaded)

`ndbmt` is a multi-threaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmt` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmt` functions

in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmt` differs from `ndbd`, and you should consult [Section 16.4.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), for additional information about running MySQL Cluster data nodes that apply to both the single-threaded and multi-threaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmt`. For more information about these options and parameters, see [Section 16.4.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), and [Section 16.3.2.6, “Defining MySQL Cluster Data Nodes”](#), respectively.

`ndbmt` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmt`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmt` to run in multi-threaded fashion.) Similarly, an `ndbmt` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multi-threaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmt` differs from using `ndbd` in two key respects:

1. You must set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter in the `config.ini` file. If you do not do so, `ndbmt` runs in single-threaded mode; that is, it behaves like `ndbd`.
2. Trace files are generated by critical errors in `ndbmt` processes in a somewhat different fashion from how these are generated by `ndbd` failures.

These differences are discussed in more detail in the next few paragraphs.

**Number of execution threads.** The `MaxNoOfExecutionThreads` configuration parameter is used to determine the number of local query handler (LQH) threads spawned by `ndbmt`. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmt` and does not apply to `ndbd`.

This parameter takes an integer value from 2 to 8 inclusive. Generally, you should set this parameter equal to the number of CPU cores on the data node host, as shown in the following table:

Number of Cores	Recommended <code>MaxNoOfExecutionThreads</code> Value
2	2
4	4
8 or more	8

(It is possible to set this parameter to other values within the permitted range, but these are automatically rounded as shown in the **Value Used** column of the next table in this section.)

The multi-threaded data node process always spawns at least 4 threads, listed here:

- 1 local query handler (LQH) thread
- 1 transaction coordinator (TC) thread
- 1 transporter thread
- 1 subscription manager (SUMA) thread

Setting this parameter to a value between 4 and 8 inclusive causes additional LQH threads to be used by `ndbmt` (up to a maximum of 4 LQH threads), as shown in the following table:

<code>config.ini</code> Value	Value Used	Number of LQH Threads Used
3	2	1
5 or 6	4	2
7	8	4

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `ERROR LINE NUMBER: ILLEGAL VALUE VALUE FOR PARAMETER MAXNOOFEXECUTIONTHREADS`.

This parameter has a default value of 2.

Currently it is not possible to cause `ndbmt` to use more than 1 TC thread, although we plan to introduce this capability in a future MySQL Cluster release series.

Like `ndbd`, `ndbmt` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmt` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the MySQL Cluster Development and Support teams. One trace file is generated for each `ndbmt` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmt` process running as a MySQL Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmt`. See [ndbd Error Messages](#), for a listing of these.

#### Note

It is possible to use `ndbd` and `ndbmt` concurrently on different data nodes in the same MySQL Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

## 16.4.4. `ndb_mgmd` — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the MySQL Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.10. `ndb_mgmd` Command Line Options**

Format	Description	Introduc- tion	Deprecated	Removed
<code>--bind-address</code>	Local bind address			
<code>--config-cache=value</code>	Enable the management server configuration cache; ON by default.			
<code>-c</code>	Specify the cluster configuration file; in NDB-6.4.0 and later, needs <code>--reload</code> or <code>--initial</code> to override configuration cache if present			
<code>--configdir=directory</code>	Specify the cluster management server's configuration cache directory			
<code>--daemon</code>	Run <code>ndb_mgmd</code> in daemon mode (default)			
<code>--initial</code>	Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache			
<code>--install[=name]</code>	Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.			
<code>--interactive</code>	Run <code>ndb_mgmd</code> in interactive mode (not officially supported in			

Format	Description	Introduc- tion	Deprecated	Removed
	production; for testing purposes only)			
<code>--log-name=</code>	A name to use when writing messages applying to this node in the cluster log.			
<code>--mycnf</code>	Read cluster configuration data from the my.cnf file			
<code>--no-nodeid-checks</code>	Do not provide any node id checks			
<code>--nodaemon</code>	Do not run ndb_mgmd as a daemon			
<code>--nowait-nodes=list</code>	Do not wait for these management nodes when starting this management server. Also requires <code>--ndb-nodeid</code> to be used.			
<code>--print-full-config</code>	Print full configuration and exit			
<code>--reload</code>	Causes the management server to compare the configuration file with its configuration cache			
<code>--remove[=name]</code>	Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.			

- `--bind-address=host[:port]`

Command-Line Format	<code>--bind-address</code>		
	Permitted Values		
	Type	<code>string</code>	
	Default	<code>[none]</code>	

When specified, this option limits management server connections by management clients to clients at the specified host name or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `UNABLE TO SETUP PORT: HOST:PORT!`

If the `port` is not specified, the management client attempts to use port 1186.

- `--no-nodeid-checks`

Command-Line Format	<code>--no-nodeid-checks</code>		
	Permitted Values		
	Type	<code>boolean</code>	
	Default	<code>FALSE</code>	

Do not perform any checks of node IDs.

- `--configdir=path`

Command-Line Format	<code>--configdir=directory</code>		
	<code>--config-dir=directory</code>		
	Permitted Values		
	Type	<code>file name</code>	
	Default	<code>\$INSTALLDIR/mysql-cluster</code>	

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

- This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that

it reads its configuration from `config.ini` every time it starts (see [Section 16.3.2, “MySQL Cluster Configuration Files”](#)). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`
- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

- `--config-file=filename, -f filename`

Command-Line Format	<code>--config-file</code>	
	<code>-f</code>	
	<code>-c</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>./config.ini</code>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. This option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See [Section 16.3.2, “MySQL Cluster Configuration Files”](#), for more information.

- `--mycnf`

Command-Line Format	<code>--mycnf</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Read configuration data from the `my.cnf` file.

- `--daemon, -d`

<b>Command-Line Format</b>	<code>--daemon</code>	
	<code>-d</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>TRUE</code>

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--interactive`

<b>Command-Line Format</b>	<code>--interactive</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other MySQL Cluster nodes.

- `--initial`

<b>Command-Line Format</b>	<code>--initial</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see [Section 16.3.2, “MySQL Cluster Configuration Files”](#)). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same MySQL Cluster and tries to use the other management server's configuration data; `ndb_mgmd` ignores `--initial` unless it is the only management server running. This behavior also has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#), for more information.

- `--log-name=name`

<b>Command-Line Format</b>	<code>--log-name=</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>MgmtSrvr</code>

Provides a name to be used for this node in the cluster log.

- `--nodaemon`

Command-Line Format	<code>--nodaemon</code>	
	Permitted Values	
	Type	boolean
	Default	FALSE
	Permitted Values	
	Type (windows)	boolean
	Default	TRUE

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- `--print-full-config, -P`

Command-Line Format	<code>--print-full-config</code>	
	<code>-P</code>	
	Permitted Values	
	Type	boolean
	Default	FALSE

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

Command-Line Format	<code>--reload</code>	
	Permitted Values	
	Type	boolean
	Default	FALSE

In MySQL Cluster NDB 7.2, configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 16.3.2, “MySQL Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When a management server starts, it checks for another management server in the same MySQL Cluster and tries to use the other management server's configuration data; `ndb_mgmd` ignores `--reload` unless it is the only management server running. This behavior also has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#), for more information.

- `--nowait-nodes`

Command-Line Format	<code>--nowait-nodes=list</code>
---------------------	----------------------------------

	Permitted Values	
	Type	numeric
	Default	
	Range	1 .. 255

When starting a MySQL Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own.

However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 192.168.0.101

[ndbd]
NodeId = 2
HostName = 192.168.0.102

[ndbd]
NodeId = 3
HostName = 192.168.0.103

[ndbd]
NodeId = 4
HostName = 192.168.0.104

[ndb_mgmd]
NodeId = 10
HostName = 192.168.0.150

[ndb_mgmd]
NodeId = 11
HostName = 192.168.0.151

[api]
NodeId = 20
HostName = 192.168.0.200

[api]
NodeId = 21
HostName = 192.168.0.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 192.168.0.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 192.168.0.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connectstring that references both management servers, like this:

```
shell> ndbd -c 192.168.0.150,192.168.0.151
```

The same is true with regard to the connectstring used with any `mysqld` processes that you wish to start as MySQL Cluster SQL nodes connected to this cluster. See [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#), for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmt` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same MySQL Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

### Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#), for information about using connectstrings. [Section 16.4.4, “ndb\\_mgmd — The MySQL Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 16.3, “MySQL Cluster Configuration”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 16.5, “Management of MySQL Cluster”](#).

When the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.
- `--install[=name]`

Command-Line Format	<code>--install[=name]</code>	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>ndb_mgmd</code>

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--remove[=name]`

Command-Line Format	<code>--remove[=name]</code>
---------------------	------------------------------

	Permitted Values	
	Type	<code>string</code>
	Default	<code>ndb_mgmd</code>

Causes an `ndb_mgmd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndb_mgmd`.

The `--remove` option has no effect on non-Windows platforms.

## 16.4.5. `ndb_mgm` — The MySQL Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the MySQL Cluster management client program `ndb_mgm`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.11. `ndb_mgm` Command Line Options**

Format	Description	Introduc- tion	Deprecat- ed	Removed
<code>--execute=name</code>	Execute command and exit			
<code>--try-reconnect=#</code>	Specify number of tries for connecting to <code>ndb_mgmd</code> (0 = infinite)			

- `--execute=command, -e command`

Command-Line Format	<code>--execute=name</code>
	<code>-e</code>

This option can be used to send a command to the MySQL Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.2.3.1, “Using Options on the Command Line”](#).

### Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--try-reconnect=number`

Command-Line Format	<code>--try-reconnect=#</code>	
	<code>-t</code>	
	Permitted Values	
	Type	boolean
	Default	TRUE

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

Additional information about using `ndb_mgm` can be found in [Section 16.5.2, “Commands in the MySQL Cluster Management Client”](#).

## 16.4.6. `ndb_config` — Extract MySQL Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: a MySQL Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

The following table includes options that are specific to `ndb_config`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.12. `ndb_config` Command Line Options**

Format	Description	Introduc- tion	Deprecated	Removed
<code>--config-file=path</code>	Set the path to <code>config.ini</code> file			
<code>--config_from_node=#</code>	Obtain configuration data from the node having this ID (must be a data node).			
<code>--configinfo</code>	Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output.			
<code>--connections</code>	Print CONNECTIONS section information only. Cannot be used with <code>--nodes</code> or <code>--system</code> option.			
<code>--fields=string</code>	Field separator			
<code>--host=name</code>	Specify host			
<code>--mycnf</code>	Read configuration data from <code>my.cnf</code> file			
<code>--nodeid</code>	Get configuration of node with this ID			
<code>--nodes</code>	Print node information (DB section) only.			
<code>-c</code>	Short form for <code>--ndb-connectstring</code>			
<code>--query=string</code>	One or more query options (attributes)			
<code>--rows=string</code>	Row separator			

Format	Description	Introduc- tion	Deprecated	Removed
<code>--system</code>	Print SYSTEM section information only. Cannot be used with <code>-nodes</code> or <code>--connections</code> option.			
<code>--type=name</code>	Specify node type			
<code>--configinfo --xml</code>	Use <code>--xml</code> with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values.			

- `--usage`, `--help`, or `-?`

Command-Line Format	<code>--help</code>
	<code>--usage</code>
	<code>-?</code>

Causes `ndb_config` to print a list of available options, and then exit.

- `--config_from_node=#`

Command-Line Format	<code>--config_from_node=#</code>	
	<b>Permitted Values</b>	
	Type	numeric
	Default	none
	Range	1 .. 48

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--version`, `-V`

Command-Line Format	<code>--version</code>
	<code>-V</code>

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connect_string`, `-c connect_string`

Specifies the connectstring to use in connecting to the management server. The format for the connectstring is the same as described in [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#), and defaults to `localhost:1186`.

- `--config-file=path-to-file`

Command-Line Format	<code>--config-file=path</code>	
	<b>Permitted Values</b>	
	Type	file name
	Default	

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--mycnf`

<b>Command-Line Format</b>	<code>--mycnf</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Read configuration data from the `my.cnf` file.

- `--query=query-options, -q query-options`

<b>Command-Line Format</b>	<code>--query=string</code>	
	<code>-q</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `id` (node ID), `type` (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` returns the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

#### Note

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

<b>Command-Line Format</b>	<code>--host=name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Specifies the host name of the node for which configuration information is to be obtained.

#### Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all MySQL Cluster configuration values relating to hosts, or verify that all MySQL Cluster hosts handle `localhost` in the same fashion.

- `--id=node_id`  
`--nodeid=node_id`

Either of these options can be used to specify the node ID of the node for which configuration information is to be obtained. `--nodeid` is the preferred form.

- `--nodes`

<b>Command-Line Format</b>	<code>--nodes</code>
----------------------------	----------------------

	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Tells `ndb_config` to print information from parameters defined in `DB` sections only. This option cannot be used together with `--connections` or `--system`.

- `--connections`

<b>Command-Line Format</b>	<code>--connections</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Tells `ndb_config` to print `CONNECTIONS` information only. This option cannot be used together with `--nodes` or `--system`.

- `--system`

<b>Command-Line Format</b>	<code>--system</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Tells `ndb_config` to print `SYSTEM` information only.

This option cannot be used together with the `--nodes` or `--system` options.

- `--type=node_type`

<b>Command-Line Format</b>	<code>--type=name</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	
	<b>Valid Values</b>	ndbd mysqld ndb_mgmd

Filters results so that only configuration values applying to nodes of the specified `node_type` (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--fields=delimiter, -f delimiter`

<b>Command-Line Format</b>	<code>--fields=string</code>	
	<code>-f</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	

Specifies a *delimiter* string used to separate the fields in the result. The default is “,” (the comma character).

#### Note

If the *delimiter* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--rows=separator, -r separator`

Command-Line Format	<code>--rows=string</code>	
	<code>-r</code>	
	Permitted Values	
	Type	<code>string</code>
	Default	

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

#### Note

If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each MySQL Cluster configuration parameter supported by the MySQL Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- A brief description of the parameter's purpose, effects, and usage
- MySQL Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

***** SYSTEM *****

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

...
```

`--configinfo --xml`

Command-Line Format	<code>--configinfo --xml</code>	
	Permitted Values	
	Type	boolean
	Default	false

You can obtain the output of `ndb_config --configinfo` as XML by adding the `--xml` option. A portion of the resulting output is shown in this example:

```
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="mysql-5.1.34 ndb-7.0.6"
                  ndbversion="458758" ndbversionmajor="7" ndbversionminor="0"
                  ndbversionbuild="6">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="NDBD">
    <param name="MaxNoOfSubscriptions" comment="Max no of subscriptions (default 0 == MaxNoOfTables)"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="MaxNoOfSubscribers" comment="Max no of subscribers (default 0 == 2 * MaxNoOfTables)"
      type="unsigned" default="0" min="0" max="4294967039"/>
    ...
  </section>
  ...
</configvariables>
```

### Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
      restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

### Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the MySQL Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running MySQL Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` or `--xml` is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored.

However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the MySQL Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

## Examples

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=: --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysql
7:mysql
8:mysql
9:mysql
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connectstring that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini --query=hostname,portnumber --fields=: --rows='\n'
192.168.0.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

### 16.4.7. `ndb_cpced` — Automate Testing for NDB Development

A utility having this name was formerly part of an internal automated test framework used in testing and debugging MySQL Cluster. It was deprecated in MySQL Cluster NDB 7.0, and removed from MySQL Cluster distributions provided by Oracle beginning with MySQL Cluster NDB 7.2.1.

### 16.4.8. `ndb_delete_all` — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

#### Usage

```
ndb_delete_all -c connect_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

## Additional Options

- `--transactional,-t`

Use of this option causes the delete operation to be performed as a single transaction.

### Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

## 16.4.9. `ndb_desc` — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

### Usage

```
ndb_desc -c connect_string tbl_name -d db_name [-p]
```

### Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT(11) NOT NULL,
  weight_gm INT(11) NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
  ('','guppy', 35, 2), ('','tuna', 2500, 150000),
  ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
  ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 311
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=MEMORY
weight_gm Int NOT NULL AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex
-- Per partition info --
```

Partition	Row count	Commit count	Frag fixed memory	Frag var sized memory	Extent_space	Free extent_space
0	2	2	32768	32768	0	0
1	4	4	32768	32768	0	0

NDBT\_ProgramExit: 0 - OK

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;

ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDB;

CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see [Section 16.5.11.1, “MySQL Cluster Disk Data Objects”](#), as well as [Section 12.1.14, “CREATE LOGFILE GROUP Syntax”](#), and [Section 12.1.18, “CREATE TABLESPACE Syntax”](#).)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT(11) NOT NULL,
  weight_gm INT(11) NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
  ('','guppy', 35, 2), ('','tuna', 2500, 150000),
  ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
  ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 3
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 321
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
```

```
weight_gm Int NOT NULL AT=FIXED ST=DISK

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex

-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag var sized memory Extent_space Free extent_space
0          2          2          32768          32768          1048576      1044440
1          4          4          32768          32768          1048576      1044400

NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words,  $1048576 - 1044440 = 4136$  bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

## Additional Options

- `--extra-partition-info, -p`

Print additional information about the table's partitions.

- `--blob-info, -b`

Include information about subordinate `BLOB` and `TEXT` columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--extra-node-info, -n`

Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in MySQL Cluster.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

## 16.4.10. `ndb_drop_index` — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

### Usage

```
ndb_drop_index -c connect_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

## Additional Options

None that are specific to this application.

### Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
```

```

Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.61-ndb-7.1.20

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a                 |
| bt1               |
| bt2               |
| dogs              |
| employees         |
| fish              |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): GOT ERROR 4243 'INDEX NOT FOUND' FROM NDBCLUSTER

```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 16.4.11, “ndb\\_drop\\_table — Drop an NDB Table”](#)) to drop the table.

### 16.4.11. `ndb_drop_table` — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error `723: NO SUCH TABLE EXISTS`.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

#### Usage

```
ndb_drop_table -c connect_string tbl_name -d db_name
```

#### Additional Options

None.

### 16.4.12. `ndb_error_reporter` — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.*

#### Usage

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (`config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

If the `--fs` is used, then the data node file systems are also copied to the management host and included in the archive that is produced by this script. As data node file systems can be extremely large even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

Command-Line Format	<code>--fs</code>	
	Permitted Values	
	Type	boolean
	Default	FALSE

### 16.4.13. `ndb_print_backup_file` — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

#### Usage

```
ndb_print_backup_file file_name
```

*file\_name* is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 16.5.3.1, “MySQL Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

#### Additional Options

None.

### 16.4.14. `ndb_print_schema_file` — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

#### Usage

```
ndb_print_schema_file file_name
```

*file\_name* is the name of a cluster schema file. For more information about cluster schema files, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_schema_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

#### Additional Options

None.

### 16.4.15. `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from a MySQL Cluster system file.

#### Usage

```
ndb_print_sys_file file_name
```

*file\_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb-#_fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

#### Additional Options

None.

## 16.4.16. `ndbd_redo_log_reader` — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndbd_redo_log_reader` is intended for use primarily by MySQL Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future MySQL Cluster releases.

The C++ source files for `ndbd_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the MySQL Cluster program `ndbd_redo_log_reader`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.13. `ndbd_redo_log_reader` Command Line Options**

Format	Description	Introduc- tion	Deprecated	Removed
<code>-nocheck</code>	Do not check records for errors			
<code>-noprint</code>	Do not print records			

## Usage

```
ndbd_redo_log_reader file_name [options]
```

*file\_name* is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_#_fs/D#/LCP/#/T#F#.Data`. In each case, the `#` represents a number (not necessarily the same number). For more information, see [Cluster Data Node FileSystem-Dir Files](#).

The name of the file to be read may be followed by one or more of the options listed here:

- | Command-Line Format | <code>-noprint</code>             |
|---------------------|-----------------------------------|
|                     | <b>Permitted Values</b>           |
|                     | <b>Type</b> <code>boolean</code>  |
|                     | <b>Default</b> <code>FALSE</code> |

`-noprint`: Do not print the contents of the log file.

- | Command-Line Format | <code>-nocheck</code>             |
|---------------------|-----------------------------------|
|                     | <b>Permitted Values</b>           |
|                     | <b>Type</b> <code>boolean</code>  |
|                     | <b>Default</b> <code>FALSE</code> |

`-nocheck`: Do not check the log file for errors.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndbd_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## 16.4.17. `ndb_restore` — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 16.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

### Note

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 16.5.7, “MySQL Cluster Single User Mode”](#), for more information.

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.14. `ndb_restore` Command Line Options**

Format	Description	Introduc- tion	Deprecated	Removed
<code>--append</code>	Append data to a tab-delimited file			
<code>--backup_path=path</code>	Path to backup files directory			
<code>--backupid=#</code>	Restore from the backup with the given ID			
<code>--connect</code>	Same as connectstring			
<code>--disable-indexes</code>	Causes indexes from a backup to be ignored; may decrease time needed to restore data.			
<code>--dont_ignore_systab_0</code>	Do not ignore system table during restore. Experimental only; not for production use			
<code>- -ex- clude-databases=db-list</code>	List of one or more databases to exclude (includes those not named)			
<code>- -ex- clude-missing-columns</code>	Causes columns from the backup version of a table that are missing from the version of the table in the database to be ignored.			
<code>- -exclude-tables=table-list</code>	List of one or more tables to exclude (includes those in same database that are not named); each table reference must include the database name			
<code>--fields-enclosed-by=char</code>	Fields are enclosed with the indicated character			
<code>- - fields-option- ally-enclosed-by</code>	Fields are optionally enclosed with the indicated character			
<code>- - fields-terminated-by=char</code>	Fields are terminated by the indicated character			
<code>--hex</code>	Print binary types in hexadecimal format			
<code>- -in- clude-databases=db-list</code>	List of one or more databases to restore (excludes those not named)			
<code>--include-tables=table-list</code>	List of one or more tables to restore (excludes those in same database that are not named); each table reference must include the database name			
<code>- -lines-terminated-by=char</code>	Lines are terminated by the indicated character			

Format	Description	Introduc- tion	Deprecated	Removed
<a href="#">--lossy-conversions</a>	Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup			
<a href="#">- -ndb-nodegroup-map=map</a>	Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)			
<a href="#">--no-binlog</a>	If a mysqld is connected and using binary logging, do not log the restored data			
<a href="#">--no-restore-disk-objects</a>	Do not restore objects relating to Disk Data			
<a href="#">--no-upgrade</a>	Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes			
<a href="#">--nodeid=#</a>	Back up files from node with this ID			
<a href="#">--parallelism=#</a>	Number of parallel transactions to use while restoring data			
<a href="#">--preserve-trailing-spaces</a>	Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types			
<a href="#">--print</a>	Print metadata, data and log to stdout (equivalent to --print_meta -print_data --print_log)			
<a href="#">--print_data</a>	Print data to stdout			
<a href="#">--print_log</a>	Print to stdout			
<a href="#">--print_metadata</a>	Print metadata to stdout			
<a href="#">--progress-frequency=#</a>	Print status of restoration each given number of seconds			
<a href="#">--promote-attributes</a>	Allow attributes to be promoted when restoring data from backup			
<a href="#">--rebuild-indexes</a>	Causes multi-threaded ordered index rebuilding of indexes found in the backup.			
<a href="#">--restore_data</a>	Restore table data and logs into NDB Cluster using the NDB API			
<a href="#">--restore_epoch</a>	Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.			
<a href="#">--restore_meta</a>	Restore metadata to NDB Cluster using the NDB API			
<a href="#">- -re- write-data- base=olddb,newdb</a>	Restores to a database with a different name than the original			
<a href="#">--skip-broken-objects</a>	Causes missing blob tables in the backup file to be ignored.			
<a href="#">--skip-table-check</a>	Skip table structure check during restoring of data			
<a href="#">--skip-unknown-objects</a>	Causes schema objects not recognized by ndb_restore to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version.			
<a href="#">--tab=path</a>	Creates a tab-separated .txt file for each table in the given path			
<a href="#">--verbose=#</a>	Level of verbosity in output			

Typical options for this utility are shown here:

```
ndb_restore [-c connectstring] -n node_id [-m] -b backup_id \
-r --backup_path=/path/to/backup/files
```

The `-c` option is used to specify a connectstring which tells `ndb_restore` where to locate the cluster management server. (See [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#), for information on connectstrings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 16.3.2.7, “Defining SQL and](#)

Other API Nodes in a MySQL Cluster”).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

`-n` is used to specify the node ID of the data node on which the backups were taken.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `-m` option. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore. You should also remove manually any Disk Data files present in the data node's `DataDir`.)

It is possible to restore data without restoring table metadata. The default behavior when doing this is for `ndb_restore` to fail with an error if table data do not match the table schema; this can be overridden using the `--skip-table-check` or `-s` option.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

`ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See [Section 15.4.1.6.2, “Replication of Columns Having Different Data Types”](#), for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

`--lossy-conversions, -L`

Command-Line Format	<code>--lossy-conversions</code>	
	<code>-L</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see [Section 15.4.1.6.2, “Replication of Columns Having Different Data Types”](#), for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

The `--preserve-trailing-spaces` option (short form `-R`) causes trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR` or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

### Note

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 16.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#).)

### Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

`--restore_epoch` (short form: `-e`) adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on a MySQL Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 16.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#).)

`--restore_data` causes `ndb_restore` to output NDB table data and logs.

This option causes `ndb_restore` to print NDB table metadata.

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup_path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 16.2.7, “Upgrading and Downgrading MySQL Cluster NDB 7.2”](#), for more information.

### Important

It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer MySQL Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running MySQL Cluster NDB 7.1.8 to a cluster running MySQL Cluster NDB 7.0.16, you must use the `ndb_restore` that comes with the MySQL Cluster NDB 7.1.8 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden using the `--no-upgrade` option (short form: `-u`) when running `ndb_restore`.

`--print_data`

The `--print_data` option causes `ndb_restore` to direct its output to `stdout`.

`TEXT` and `BLOB` column values are always truncated to the first 256 bytes in the output; this cannot currently be overridden when us-

ing `--print_data`.

Several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following list:

- `--tab, -T`

<b>Command-Line Format</b>	<code>--tab=path</code>
	<code>-T</code>

This option causes `--print_data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--fields-enclosed-by=string`

<b>Command-Line Format</b>	<code>--fields-enclosed-by=char</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Each column values are enclosed by the string passed to this option (regardless of data type; see next item).

- `--fields-optionally-enclosed-by=string`

<b>Command-Line Format</b>	<code>--fields-optionally-enclosed-by</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=string`

<b>Command-Line Format</b>	<code>--fields-terminated-by=char</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>\t (tab)</code>

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--hex`

<b>Command-Line Format</b>	<code>--hex</code>
----------------------------	--------------------

If this option is used, all binary values are output in hexadecimal format.

- `--fields-terminated-by=string`

<b>Command-Line Format</b>	<code>--fields-terminated-by=char</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>\t (tab)</code>

This option specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--append`

<b>Command-Line Format</b>	<code>--append</code>
----------------------------	-----------------------

When used with the `--tab` and `--print_data` options, this causes the data to be appended to any existing files having the same names.

### Note

If a table has no explicit primary key, then the output generated when using the `--print_data` option includes the table's hidden primary key.

### `--print_metadata`

This option causes `ndb_restore` to print all metadata to `stdout`.

### `--print_log`

The `--print_log` option causes `ndb_restore` to output its log to `stdout`.

### `--print`

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print_data`, `--print_metadata`, and `--print_log` options together.

### `--dont_ignore_systab_0`

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont_ignore_systab_0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

### `--ndb-nodegroup-map, -z`

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group, target_node_group`.

### `--no-binlog`

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

### `--no-restore-disk-objects, -d`

This option stops `ndb_restore` from restoring any MySQL Cluster Disk Data objects, such as tablespaces and log file groups; see [Section 16.5.11, “MySQL Cluster Disk Data Tables”](#), for more information about these.

### `--parallelism=#, -p`

Determines the maximum number of parallel transactions that `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

### `--progress-frequency=N`

Print a status report each `N` seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

### `--verbose=#`

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

It is possible to restore only selected databases, or selected tables from a single database, using the syntax shown here:

```
ndb_restore other_options db_name[,db_name][...] | tbl_name[,tbl_name][...]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

```
--include-databases=db_name[,db_name][...]
```

Command-Line Format	--include-databases=db-list	
	Permitted Values	
	Type	string
	Default	

```
--include-tables=db_name.tbl_name[,db_name.tbl_name][...]
```

Command-Line Format	--include-tables=table-list	
	Permitted Values	
	Type	string
	Default	

Use the `--include-databases` option or the `--include-tables` option for restoring only specific databases or tables, respectively. `--include-databases` takes a comma-delimited list of databases to be restored. `--include-tables` takes a comma-delimited list of tables (in `database.table` format) to be restored.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from a MySQL Cluster backup:

Option Used	Result
<code>--include-databases=db1</code>	Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored
<code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code> )	Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored
<code>--include-tables=db1.t1</code>	Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored
<code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code> )	Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code> , <code>db2</code> , or any other database are restored

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

```
--exclude-databases=db_name[,db_name][...]
```

Command-Line Format	--exclude-databases=db-list	
---------------------	-----------------------------	--

	Permitted Values	
	Type	string
	Default	

```
--exclude-tables=db_name.tbl_name[,db_name.tbl_name][,...]
```

Command-Line Format	<code>--exclude-tables=table-list</code>	
	Permitted Values	
	Type	string
	Default	

It is possible to prevent one or more databases or tables from being restored using the `ndb_restore` options `--exclude-databases` and `--exclude-tables`. `--exclude-databases` takes a comma-delimited list of one or more databases which should not be restored. `--exclude-tables` takes a comma-delimited list of one or more tables (using `database.table` format) which should not be restored.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from a MySQL Cluster backup:

Option Used	Result
<code>--exclude-databases=db1</code>	All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored
<code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code> )	All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored
<code>--exclude-tables=db1.t1</code>	All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored
<code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code> )	All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored

You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, along with the tables `t1` and `t2` in database `db3`, *not* to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

`--exclude-missing-columns`

<b>Command-Line Format</b>	<code>--exclude-missing-columns</code>
----------------------------	--

It is also possible to restore only selected table columns using the `--exclude-missing-columns` option. When this option is used, `ndb_restore` ignores any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the options described in the previous paragraph to do so, then restore data to the remaining tables using a complementary set of these options.

`--disable-indexes`

<b>Command-Line Format</b>	<code>--disable-indexes</code>
----------------------------	--------------------------------

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multi-threaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

`--rebuild-indexes`

<b>Command-Line Format</b>	<code>--rebuild-indexes</code>
----------------------------	--------------------------------

You can use this option with `ndb_restore` to cause multi-threaded rebuilding of the ordered indexes while restoring a native NDB backup.

`--skip-broken-objects`

<b>Command-Line Format</b>	<code>--skip-broken-objects</code>
----------------------------	------------------------------------

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

`--skip-unknown-objects`

<b>Command-Line Format</b>	<code>--skip-unknown-objects</code>
----------------------------	-------------------------------------

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running MySQL Cluster NDB 7.2 to a cluster running MySQL Cluster NDB 7.1.

`--rewrite-database=old_dbname, new_dbname`

<b>Command-Line Format</b>	<code>--rewrite-database=olddb, newdb</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	none

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown

here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

### Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

**Error reporting.** `ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

### Important

After using `ndb_restore` to initialize a MySQL Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in MySQL Cluster.

## 16.4.18. `ndb_select_all` — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

### Usage

```
ndb_select_all -c connect_string tbl_name -d db_name [> file_name]
```

### Additional Options

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--header=FALSE`  
Excludes column headers from the output.
- `--useHexFormat -x`  
Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.
- `--delimiter=character, -D character`  
Causes the *character* to be used as a column delimiter. Only table data columns are separated by this delimiter.  
The default delimiter is the tab character.
- `--disk`  
Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.
- `--rowid`  
Adds a `ROWID` column providing information about the fragments in which rows are stored.
- `--gci`  
Adds a column to the output showing the global checkpoint at which each row was last updated. See [Section 16.1, “MySQL Cluster Overview”](#), and [Section 16.5.5.2, “MySQL Cluster Log Events”](#), for more information about checkpoints.
- `--tupscan, -t`  
Scan the table in the order of the tuples.
- `--nodata`  
Causes any table data to be omitted.

## Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+-----+-----+
| id | name |
+-----+-----+
| 3 | shark |
| 6 | puffer |
| 2 | tuna |
| 4 | manta ray |
| 5 | grouper |
| 1 | guppy |
+-----+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
NDBT_ProgramExit: 0 - OK
```

Note that all string values are enclosed by square brackets (“[...]”) in the output of `ndb_select_all`. For a further example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
  PRIMARY KEY pk (id),
  KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
  ('', 'Lassie', 'collie'),
  ('', 'Scooby-Doo', 'Great Dane'),
  ('', 'Rin-Tin-Tin', 'Alsatian'),
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI      id name      breed      DISK_REF
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878   4 [Rosscoe]    [Mutt]      [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463   3 [Rin-Tin-Tin] [Alsatian] [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657   1 [Lassie]     [Collie]    [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

## 16.4.19. `ndb_select_count` — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

### Usage

```
ndb_select_count [-c connect_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

### Additional Options

None that are specific to this application. However, you can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

### Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

## 16.4.20. `ndb_show_tables` — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and MySQL Cluster Disk Data objects as well.

The following table includes options that are specific to the MySQL Cluster program `ndb_show_tables`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.15. `ndb_show_tables` Command Line Options**

Format	Description	Introduc- tion	Deprecated	Removed
<code>--database=string</code>	Specifies the database in which the table is found			
<code>--loops=#</code>	Number of times to repeat output			
<code>--parsable</code>	Return output suitable for MySQL LOAD DATA INFILE statement			

Format	Description	Introduc- tion	Deprecated	Removed
<a href="#">--show-temp-status</a>	Show table temporary flag			
<a href="#">--type=#</a>	Limit output to objects of this type			
<a href="#">--unqualified</a>	Do not qualify table names			

## Usage

```
ndb_show_tables [-c connect_string]
```

- [--database, -d](#)  
Specifies the name of the database in which the tables are found.
- [--loops, -l](#)  
Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.
- [--parsable, -p](#)  
Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.
- [--show-temp-status](#)  
If specified, this causes temporary tables to be displayed.
- [--type, -t](#)  
Can be used to restrict the output to one type of object, specified by an integer type code as shown here:
  - 1: System table
  - 2: User-created table
  - 3: Unique hash index
 Any other value causes all NDB database objects to be listed (the default).
- [--unqualified, -u](#)  
If specified, this causes unqualified object names to be displayed.

### Note

Only user-created MySQL Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see [Section 16.4.18, “ndb\\_select\\_all — Print Rows from an NDB Table”](#)).

## 16.4.21. `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

## Requirements

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.

- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`. If this file is not present in your MySQL installation, you can obtain it from the [MySQL Forge project page](#).

The following table includes options that are specific to the MySQL Cluster program `ndb_size.pl`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 16.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 16.16. `ndb_size.pl` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>--database=dbname</code>	The database or databases to examine; accepts a comma-delimited list; the default is <code>ALL</code> (use all databases found on the server)			
<code>--excludedbs=db-list</code>	Skip any databases in a comma-separated list of databases			
<code>--excludetables=tbl-list</code>	Skip any tables in a comma-separated list of tables			
<code>--format=string</code>	Set output format (text or HTML)			
<code>--hostname[:port]</code>	Specify host and optional port as <code>host[:port]</code>			
<code>--loadqueries=file</code>	Loads all queries from the file specified; does not connect to a database			
<code>--password=string</code>	Specify a MySQL user password			
<code>--real_table_name=table</code>	Designates a table to handle unique index size calculations			
<code>--savequeries=file</code>	Saves all queries to the database into the file specified			
<code>--socket=file</code>	Specify a socket to connect to			
<code>--user=string</code>	Specify a MySQL user name			

## Usage

```
perl ndb_size.pl db_name [ALL] [--hostname=host[:port]] [--socket=socket] [--user=user] \
  [--password=password] [--help|-h] [--format=(html|text)] [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name (and possibly a port as well) can be specified using `--hostname`; the default is `localhost:3306`. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-----
Connected to: DBI:mysql:host=localhost:mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1
-----
DataMemory for Columns (* means var sized DataMemory):
  Column Name      Type      Var sized  Key      4.1      5.0      5.1
  -----
  HIDDEN_NDB_PKEY  bigint    Y          PRI      8        8        8
  c2               varchar(50) Y          Y        52       52      4*
  c1               int(11)    Y          Y        4        4        4
  --             --             --
```

Fixed Size Columns DM/Row				64	64	12
VarSize Columns DM/Row				0	0	4
DataMemory for Indexes:						
Index Name		Type	4.1	5.0	5.1	
PRIMARY		BTREE	16	16	16	
			--	--	--	
Total Index DM/Row			16	16	16	
IndexMemory for Indexes:						
Index Name	4.1	5.0	5.1			
PRIMARY	33	16	16			
	--	--	--			
Indexes IM/Row	33	16	16			
Summary (for THIS table):						
Fixed Overhead DM/Row	12	12	16			
NULL Bytes/Row	4	4	4			
DataMemory/Row	96	96	48	(Includes overhead, bitmap and indexes)		
VarSize Overhead DM/Row	0	0	8			
VarSize NULL Bytes/Row	0	0	4			
Avg VarSide DM/Row	0	0	16			
No. Rows	0	0	0			
Rows/32kb DM Page	340	340	680			
Fixedsize DataMemory (KB)	0	0	0			
Rows/32kb VarSize DM Page	0	0	2040			
VarSize DataMemory (KB)	0	0	0			
Rows/8kb IM Page	248	512	512			
IndexMemory (KB)	0	0	0			
Parameter Minimum Requirements						
-----						
* indicates greater than default						
Parameter	Default	4.1	5.0	5.1		
DataMemory (KB)	81920	0	0	0		
NoOfOrderedIndexes	128	1	1	1		
NoOfTables	128	1	1	1		
IndexMemory (KB)	18432	0	0	0		
NoOfUniqueHashIndexes	64	0	0	0		
NoOfAttributes	1000	3	3	3		
NoOfTriggers	768	5	5	5		

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read in during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown in this example:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.) This figure shows a portion of the generated `ndb_size.html` output file, as viewed in a Web browser:

## MySQL Cluster analysis for world

This is an automated analysis of the DBI:mysql:database=world;host=192.168.0.176 database for migration into MySQL Cluster. No warranty is made to the accuracy of the information.

This information should be valid for MySQL 4.1 and 5.0. Since 5.1 is not a final release yet, the numbers should be used as a guide only.

### Parameter Settings

**NOTE** the configuration parameters below do not take into account system tables and other requirements.

Parameter	4.1	5.0	5.1
DataMemory (kb)	544	544	544
IndexMemory (kb)	192	136	136
MaxNoOfTables	3	3	3
MaxNoOfAttributes	24	24	24
MaxNoOfOrderedIndexes	3	3	3
MaxNoOfUniqueHashIndexes	3	3	3
MaxNoOfTriggers	12	12	12

### Memory usage because of parameters

Usage is in kilobytes. Actual usage will vary as you should set the parameters larger than those listed in the table above.

Parameter	4.1	5.0	5.1
Attributes	5	5	5
Tables	60	60	60
OrderedIndexes	30	30	30
UniqueHashIndexes	45	45	45

### Table List

- [City](#)
- [Country](#)
- [CountryLanguage](#)

#### City

Column	Type	Size	Key	4.1 NDB Size	5.0 NDB Size	5.1 NDB Size
ID	int	11	PRI	4	4	4
District	char	20		20	20	20
Name	char	35		36	36	36
Population	int	11		4	4	4
CountryCode	char	3		4	4	4

### Indexes

We assume that indexes are ORDERED (not created USING HASH). If order is not required, 10 bytes of data memory can be saved per row if the index is created USING HASH

Index	Type	Columns	4.1 IdxMem	5.0 IdxMem	5.1 IdxMem	4.1 DatMem	5.0 DatMem	5.1 DatMem
PRIMARY	BTREE	ID	29	25	25	10	10	10

### DataMemory Usage

	4.1	5.0	5.1
Row Overhead	16	16	16
Column DataMemory/Row	68	68	68
Index DataMemory/Row	10	10	10
Total DataMemory/Row	94	94	94
Rows per 32 kb page	347	347	347
Current number of rows	4079	4079	4079
Total DataMemory (kb)	384	384	384

### IndexMemory Usage

	4.1	5.0	5.1
IndexMemory/Row	29	25	25
Rows per 8kb page	282	327	327
Current number of rows	4079	4079	4079
Total IndexMemory (kb)	120	104	104

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

## 16.4.22. `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- `STARTED`: The node is operational, and has joined the cluster.
- `SHUTTING_DOWN`: The node is shutting down.
- `SINGLE USER MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

**Table 16.17. `ndb_waiter` Command Line Options**

Format	Description	Introduc- tion	Deprecated	Removed
<code>--no-contact</code>	Wait for cluster to reach NO CONTACT state			
<code>--not-started</code>	Wait for cluster to reach NOT STARTED state			
<code>--nowait-nodes=list</code>	List of nodes not to be waited for.			
<code>--single-user</code>	Wait for cluster to enter single user mode			
<code>--timeout=#</code>	Wait this many seconds, then exit whether or not cluster has reached desired state; default is 2 minutes (120 seconds)			
<code>--wait-nodes=list</code>	List of nodes to be waited for.			

### Usage

```
ndb_waiter [-c connect_string]
```

### Additional Options

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before

exiting.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

### Important

Do *not* use this option together with the `--wait-nodes` option.

- `--wait-nodes=list, -w list`

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

### Important

Do *not* use this option together with the `--nowait-nodes` option.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by "...") are omitted.

```
shell> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED
```

```

...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK

```

### Note

If no connectstring is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

## 16.4.23. Options Common to MySQL Cluster Programs

All MySQL Cluster programs (except for `mysqld`) take the options described in this section. Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help` option with any MySQL Cluster program to view a list of the options which it supports.

The options in the following table are common to all MySQL Cluster executables.

**Table 16.18. Command Line Options Common to MySQL Cluster Programs**

Format	Description	Introduc- tion	Deprecated	Removed
<code>--character-sets-dir=path</code>	Directory where character sets are			
<code>--core-file</code>	Write core on errors (defaults to TRUE in debug builds)			
<code>--debug=options</code>	Enable output from debug calls. Can be used only for versions compiled with debugging enabled			
<code>--help</code>	Display help message and exit			
- - <code>ndb-connect-string=connectstring</code>	Set connectstring for connecting to <code>ndb_mgmd</code> . Syntax: <code>[nodeid=&lt;id&gt;:][host=&lt;hostname&gt;[:&lt;port&gt;]</code> . Overrides entries specified in <code>NDB_CONNECTSTRING</code> or <code>my.cnf</code> .			
- - <code>ndb-mg-md-host=host[:port]</code>	Set the host (and port, if desired) for connecting to the management server			
<code>--ndb-nodeid=#</code>	Set node id for this node			
- - <code>ndb-optimized-node-selection</code>	Select nodes for transactions in a more optimal way			
<code>--version</code>	Output version information and exit			

For options specific to individual MySQL Cluster programs, see [Section 16.4, “MySQL Cluster Programs”](#).

See [Section 16.3.4.2, “MySQL Server Options for MySQL Cluster”](#), for `mysqld` options relating to MySQL Cluster.

- `--help, --usage, -?`

<b>Command-Line Format</b>	<code>--help</code>
	<code>--usage</code>
	<code>-?</code>

Prints a short list with descriptions of the available command options.

- `--character-sets-dir=name`

<b>Command-Line Format</b>	<code>--character-sets-dir=path</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	

Tells the program where to find character set information.

- `--ndb-connectstring=connect_string, --connect-string=connect_string, -c connect_string`

<b>Command-Line Format</b>	<code>--ndb-connectstring=connectstring</code>	
	<code>--connect-string=connectstring</code>	
	<code>-c</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>localhost:1186</code>

This option takes a MySQL Cluster connectstring that specifies the management server for the application to connect to, as shown here:

```
shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#).

- `--core-file`

<b>Command-Line Format</b>	<code>--core-file</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

<b>Command-Line Format</b>	<code>--debug=options</code>
----------------------------	------------------------------

	Permitted Values	
	Type	string
	Default	d:t:0,/tmp/ndb_restore.trace

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--ndb-mgmd-host=host[:port]`

Command-Line Format	<code>--ndb-mgmd-host=host[:port]</code>	
Option-File Format	<code>ndb-mgmd-host</code>	
	Permitted Values	
	Type	string
	Default	localhost:1186

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

Command-Line Format	<code>--ndb-nodeid=#</code>	
	Permitted Values	
	Type	numeric
	Default	0

Sets this node's MySQL Cluster node ID. *The range of permitted values depends on the node's type (data, management, or API) and the MySQL Cluster software version.* See [Section 16.1.6.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#), for more information.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>	
	Permitted Values	
	Type	boolean
	Default	TRUE

Optimize selection of nodes for transactions. Enabled by default.

- `--version, -V`

Command-Line Format	<code>--version</code>
	<code>-V</code>

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster.

See [Section 16.5.4, “Performing a Rolling Restart of a MySQL Cluster”](#), for more information.

## 16.5. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in [Section 16.3, “MySQL Cluster Configuration”](#), and [Section 16.4, “MySQL Cluster Programs”](#).

The next few sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see [Section 16.5.10, “MySQL Cluster Security Issues”](#).

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about MySQL Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see [Section 16.5.9, “The ndbinfo MySQL Cluster Information Database”](#).

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by MySQL Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the `SESSION_STATUS` table or the `GLOBAL_STATUS` table (in the `INFORMATION_SCHEMA` database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on `NDB` tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

MySQL Enterprise Monitor can also be used to monitor MySQL Servers that are part of a MySQL Cluster deployment. MySQL Enterprise Monitor 2.3, added a MySQL Cluster advisor, including a set of graphs providing information on MySQL Cluster resources, and defining rules for alerts on key information from data nodes such as `DataMemory` usage. This information is made available to MySQL Enterprise Monitor 2.3 or later by any MySQL Server which is connected to the MySQL Cluster, using `ndbinfo`. The advisor could be run against a single MySQL Server in the Cluster, or against a pair in order to provide a higher level of availability for the monitoring service. For more information, see the [MySQL Enterprise Monitor 2.3 Manual](#).

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex MySQL Cluster management tasks, such as starting, stopping, or restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to MySQL Cluster. MySQL Cluster Manager 1.1 provides support for adding data nodes online. See the [MySQL Cluster Manager 1.1 User Manual](#), for more information.

### 16.5.1. Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in [MySQL Cluster Start Phases](#), in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 16.5.2, “Commands in the MySQL Cluster Management Client”](#)). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

**Start types.** There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

#### ■ Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start (see [NDB Kernel Blocks](#)). Data node file systems are cleared on those data nodes that were started with `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. MySQL Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

#### Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and

any required node takeovers are performed.

- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as *Started*. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by *DBDIIH*).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 16.5.2. Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client *ndb\_mgm*. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 16.5.5, “Event Reports Generated in MySQL Cluster”](#); commands for creating backups and restoring from them are provided in [Section 16.5.3, “Online Backup of MySQL Cluster”](#).

The management client has the following basic commands. In the listing that follows, *node\_id* denotes either a database node ID or the keyword *ALL*, which indicates that the command should be applied to all of the cluster's data nodes.

- *HELP*

Displays information on all available commands.

- *SHOW*

Displays information on the cluster's status. Possible node status values include *UNKNOWN*, *NO\_CONTACT*, *NOT\_STARTED*, *STARTING*, *STARTED*, *SHUTTING\_DOWN*, and *RESTARTING*. The output from this command also indicates when the cluster is in single user mode (status *SINGLE USER MODE*).

- *node\_id START*

Brings online the data node identified by *node\_id* (or all data nodes).

*ALL START* works on all data nodes only, and does not affect management nodes.

### **Important**

To use this command to bring a data node online, the data node must have been started using *ndbd --nostart* or *ndbd -n*.

- *node\_id STOP [-a] [-f]*

Stops the data or management node identified by *node\_id*. Note that *ALL STOP* works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated *ndbd* or *ndb\_mgmd* process terminates.

The *-a* option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, *STOP* fails if the result would cause an incomplete cluster. The *-f* option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

**Warning**

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

- `node_id RESTART [-n] [-i] [-a] [-f]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd -initial` from the system shell. Note that backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

The output from this command also indicates when the cluster is in single user mode.

- `node_id REPORT report-type`

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are two accepted values for `report-type`:

- `BackupStatus` provides a status report on a cluster backup in progress
- `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

Currently, it is not possible for data nodes to join a MySQL Cluster while it is running in single user mode. (Bug #20395)

- `EXIT SINGLE USER MODE`

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

**Note**

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no ef-

fect in this case.

- `QUIT, EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `CREATE NODEGROUP nodeid[, nodeid, ...]`

Creates a new MySQL Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to a MySQL Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each MySQL Cluster node group must have the same number of nodes). In other words, if the MySQL Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#).

- `DROP NODEGROUP nodegroup_id`

Drops the MySQL Cluster node group with the given *nodegroup\_id*.

This command can be used to drop a node group from a MySQL Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3      @10.100.2.67 (5.1.61-ndb-7.1.20, no nodegroup)
```

Prior to MySQL Cluster NDB 7.0.4, the `SHOW` output was not updated correctly following `DROP NODEGROUP`. (Bug #43413)

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see [Section 16.5.12, “Adding MySQL Cluster Data Nodes Online”](#).

### 16.5.3. Online Backup of MySQL Cluster

The next few sections describe how to prepare for and then to create a MySQL Cluster backup using the functionality for this purpose

found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” MySQL Cluster backup. (For information about the creation of backups with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).) Restoration of MySQL Cluster backups is done using the `ndb_restore` utility provided with the MySQL Cluster distribution; for information about `ndb_restore` and its use in restoring MySQL Cluster backups, see [Section 16.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#).

### 16.5.3.1. MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

### 16.5.3.2. Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 16.5.3.3, “Configuration for MySQL Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `BACKUP FAILED: FILE ALREADY EXISTS`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

A *snapshot\_option* can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous MySQL Cluster releases.

### Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a *wait\_option* and a *snapshot\_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

*backup\_id* is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node\_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, `backup_id` is the unique identifier for this particular backup, and `node_id` is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

#### Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted. Error: 1321 - Backup aborted by user request: Permanent error: User
Node 3: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is `3`, and the management node to which the cluster management client is connected has the node ID `5`. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

#### Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note**

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 16.5.3.3. Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

The amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- `BackupMaxWriteSize`

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

### 16.5.3.4. MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

**Important**

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

`NDB` does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

## 16.5.4. Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.** To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**MySQL Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more MySQL Cluster node processes are running.

**System reset (cluster reset).** To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmttd`) with the `--initial` option, which forces the data node to clear its file system and to reload all MySQL Cluster data and metadata from the other data nodes.
- Create a backup using the `ndb_mgm` client `BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See [Section 16.5.3, “Online Backup of MySQL Cluster”](#), and [Section 16.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#), for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA INFILE`.

**Resource Recovery.** To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other MySQL Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See [Rolling restarts with multiple management servers](#).)
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.
3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

The specifics for implementing a given rolling upgrade depend upon the changes being made. A more detailed view of the process is presented here:

RESTART TYPE:					
Cluster Configuration Change		Cluster Software Upgrade or Downgrade	Change on Node Host	Cluster Reset	
A. Management node (ndb_mgmd) processes...					
1. Stop all ndb_mgmd processes  2. Make changes in global configuration file(s)  3. Start all ndb_mgmd processes		1. Stop all ndb_mgmd processes  2. Replace each ndb_mgmd binary with new version  3. Start ndb_mgmd processes	1. Stop all ndb_mgmd processes  2. Make desired changes in hardware, operating system, or both  3. Start all ndb_mgmd processes	( OR )	
				1. Stop all ndb_mgmd processes  2. Start all ndb_mgmd processes	Restart all ndb_mgmd processes (optional)
B. For each data node (ndbd) process...					
( OR )		1. Stop ndbd  2. Replace ndbd binary with new version  3. Start ndbd	1. Stop ndbd  2. Make desired changes in hardware, operating system, or both  3. Start ndbd	( OR )	
1. Stop ndbd  2. Start ndbd	Restart ndbd			1. Stop ndbd  2. Start ndbd	Restart ndbd
C. For each SQL node (mysqld) process...					
( OR )		1. Stop mysqld  2. Replace mysqld binary with new version  3. Start mysqld	1. Stop mysqld  2. Make desired changes in hardware, operating system, or both  3. Start mysqld	( OR )	
1. Stop mysqld  2. Start mysqld	Restart mysqld			1. Stop mysqld  2. Start mysqld	Restart mysqld

In the previous diagram, the **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. On Windows, you can also use the system `NET START` and `NET STOP` commands or the Windows Service Manager to start and stop nodes which have been installed as Windows services (see [Section 16.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#)).

**Restart** indicates that the process may be restarted using the `ndb_mgm` management client `RESTART` command (see [Section 16.5.2, “Commands in the MySQL Cluster Management Client”](#)).

MySQL Cluster supports a flexible order for upgrading nodes. When upgrading a MySQL Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different MySQL Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of MySQL Cluster in general.)

See also Bug #48528 and Bug #49163.

**Rolling restarts with multiple management servers.** When performing a rolling restart of a MySQL Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to reread its configuration file, perform the following steps:

1. Stop all MySQL Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.
4. Start any remaining `ndb_mgmd` processes *without using either of the `--reload` or `--initial` options*.
5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See [Section 16.5.9.8, “The `ndbinfo nodes` Table”](#).

## 16.5.5. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the same directory where the `ndb_mgm` binary resides.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 16.3.2.5, “Defining a MySQL Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 1: Node 9: API 5.1.61-ndb-7.1.20
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9: API 5.1.61-ndb-7.1.20
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9: API 5.1.61-ndb-7.1.20
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 4: Node 9: API 5.1.61-ndb-7.1.20
2007-01-26 19:59:22 [MgmSrvr] ALERT      -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT      -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 16.5.5.1. MySQL Cluster Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`  
Turns the cluster log on.
- `CLUSTERLOG OFF`  
Turns the cluster log off.
- `CLUSTERLOG INFO`  
Provides information about cluster log settings.

- `node_id CLUSTERLOG category=threshold`

Logs `category` events with priority less than or equal to `threshold` in the cluster log.

- `CLUSTERLOG FILTER severity_level`

Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

The `STATISTICS` category can provide a great deal of useful data. See [Section 16.5.5.3, “Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

### Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for <code>NDBCLUSTER</code> development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER`—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

### Important

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

## 16.5.5.2. MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

### CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	INFO	Data nodes connected
data nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed
Communication opened	8	INFO	SQL node or data node connection opened

### CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk

### STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received STTORRY	15	INFO	Blocks received after completion of restart
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	INFO	Shows neighboring data nodes
data node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	INFO	NDB Cluster nodes starting

Event	Priority	Severity Level	Description
data node all start phases completed	1	INFO	NDB Cluster nodes started
data node shutdown initiated	1	INFO	Shutdown of data node has commenced
data node shutdown aborted	1	INFO	Unable to shut down data node normally

#### NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	<p>There are eight different possible results for arbitration attempts:</p> <ul style="list-style-type: none"> <li>Arbitration check failed—less than 1/2 nodes left</li> <li>Arbitration check succeeded—node group majority</li> <li>Arbitration check failed—missing node group</li> <li>Network partitioning—arbitration required</li> <li>Arbitration succeeded—affirmative response from node <i>X</i></li> <li>Arbitration failed - negative response from node <i>X</i></li> <li>Network partitioning - no arbitrator available</li> <li>Network partitioning - no arbitrator configured</li> </ul>
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i> )	7	INFO	
Report whether an arbitrator is found or not	6	INFO	<p>There are seven different possible outcomes when seeking an arbitrator:</p> <ul style="list-style-type: none"> <li>Management server restarts arbitration thread [state=<i>X</i>]</li> <li>Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>Receive arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>Started arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>]</li> </ul>

Event	Priority	Severity Level	Description
			<ul style="list-style-type: none"> <li>Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>]</li> <li>Lost arbitrator node <i>X</i> &lt;error msg&gt; [state=<i>Y</i>]</li> </ul>

### STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>
Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>
Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)

### ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	
Missed heartbeats	8	WARNING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARNING	

### INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General information events	2	INFO	

### 16.5.5.3. Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- (*Beginning with MySQL Cluster NDB 6.3.4:*) By supplying a data placement hint when the transaction is started

#### Note

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

#### Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of `Read count`. Because the value of `Simple read count` is incremented at a different point in time from `Read count`, it can lag behind `Read count` slightly, so it is conceivable that `Simple read count` is not equal to `Read count` for a given reporting interval, even if all reads made during that time were in fact simple reads.
- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

#### Note

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is  $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$ . (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 16.3.2.6, “Defining](#)

MySQL Cluster Data Nodes”).)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, **Abort count** can sometimes be greater than **Trans count**.
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

### Note

A single transaction may operate on data stored in multiple LQH blocks.

The **Operations** statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each **ndbd** process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the **NDB** management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

### Note

Setting the threshold for **STATISTICS** to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see [Section 16.5.5.1, “MySQL Cluster Logging Management Commands”](#).

## 16.5.6. MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on [NDB transporter errors](#).

### 16.5.6.1. MySQL Cluster: Messages in the Cluster Log

The following table lists the most common [NDB](#) cluster log messages. For information about the cluster log, log events, and event types, see [Section 16.5.5, “Event Reports Generated in MySQL Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The Ndb\\_logevent\\_type Type](#), for related information of interest to Cluster API developers.

<p><b>Log Message.</b> Node <i>mgm_node_id</i>: Node <i>data_node_id</i> Connected</p> <p><b>Description.</b> The data node having node ID <i>node_id</i> has connected to the management server (node <i>mgm_node_id</i>).</p>	<p><b>Event Name.</b> Connected</p> <p><b>Event Type.</b> Connection</p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>mgm_node_id</i>: Node <i>data_node_id</i> Disconnected</p> <p><b>Description.</b> The data node having node ID <i>data_node_id</i> has disconnected from the management server (node <i>mgm_node_id</i>).</p>	<p><b>Event Name.</b> Disconnected</p> <p><b>Event Type.</b> Connection</p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> ALERT</p>
<p><b>Log Message.</b> Node <i>data_node_id</i>: Communication to Node <i>api_node_id</i> closed</p> <p><b>Description.</b> The API node or SQL node having node ID <i>api_node_id</i> is no longer communicating with data node <i>data_node_id</i>.</p>	<p><b>Event Name.</b> CommunicationClosed</p> <p><b>Event Type.</b> Connection</p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>data_node_id</i>: Communication to Node <i>api_node_id</i> opened</p> <p><b>Description.</b> The API node or SQL node having node ID <i>api_node_id</i> is now communicating with data node <i>data_node_id</i>.</p>	<p><b>Event Name.</b> CommunicationOpened</p> <p><b>Event Type.</b> Connection</p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>mgm_node_id</i>: Node <i>api_node_id</i>: API version</p> <p><b>Description.</b> The API node having node ID <i>api_node_id</i> has connected to management node <i>mgm_node_id</i> using NDB API version <i>version</i> (generally the same as the MySQL version number).</p>	<p><b>Event Name.</b> ConnectedApiVersion</p> <p><b>Event Type.</b> Connection</p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: Global checkpoint <i>gci</i> started</p> <p><b>Description.</b> A global checkpoint with the ID <i>gci</i> has been started; node <i>node_id</i> is the master responsible for this global checkpoint.</p>	<p><b>Event Name.</b> GlobalCheckpointStarted</p> <p><b>Event Type.</b> Checkpoint</p> <p><b>Priority.</b> 9</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: Global checkpoint <i>gci</i> completed</p> <p><b>Description.</b> The global checkpoint having the ID <i>gci</i> has been completed;</p>	<p><b>Event Name.</b> GlobalCheckpointCompleted</p> <p><b>Event Type.</b> Checkpoint</p>

node <i>node_id</i> was the master responsible for this global checkpoint.	<b>Priority.</b> 10 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Local checkpoint <i>lcp</i> started. Keep GCI = <i>current_gci</i> oldest restorable GCI = <i>old_gci</i> <b>Description.</b> The local checkpoint having sequence ID <i>lcp</i> has been started on node <i>node_id</i> . The most recent GCI that can be used has the index <i>current_gci</i> , and the oldest GCI from which the cluster can be restored has the index <i>old_gci</i> .	<b>Event Name.</b> LocalCheckpointStarted <b>Event Type.</b> Checkpoint <b>Priority.</b> 7 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Local checkpoint <i>lcp</i> completed <b>Description.</b> The local checkpoint having sequence ID <i>lcp</i> on node <i>node_id</i> has been completed.	<b>Event Name.</b> LocalCheckpointCompleted <b>Event Type.</b> Checkpoint <b>Priority.</b> 8 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Local Checkpoint stopped in CALCULATED_KEEP_GCI <b>Description.</b> The node was unable to determine the most recent usable GCI.	<b>Event Name.</b> LCPStoppedInCalcKeepGci <b>Event Type.</b> Checkpoint <b>Priority.</b> 0 <b>Severity.</b> ALERT
<b>Log Message.</b> Node <i>node_id</i> : Table ID = <i>table_id</i> , fragment ID = <i>fragment_id</i> has completed LCP on Node <i>node_id</i> maxGciStarted: <i>started_gci</i> maxGciCompleted: <i>completed_gci</i> <b>Description.</b> A table fragment has been checkpointed to disk on node <i>node_id</i> . The GCI in progress has the index <i>started_gci</i> , and the most recent GCI to have been completed has the index <i>completed_gci</i> .	<b>Event Name.</b> LCPFragmentCompleted <b>Event Type.</b> Checkpoint <b>Priority.</b> 11 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : ACC Blocked <i>num_1</i> and TUP Blocked <i>num_2</i> times last second <b>Description.</b> Undo logging is blocked because the log buffer is close to overflowing.	<b>Event Name.</b> UndoLogBlocked <b>Event Type.</b> Checkpoint <b>Priority.</b> 7 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Start initiated <i>version</i> <b>Description.</b> Data node <i>node_id</i> , running NDB version <i>version</i> , is beginning its startup process.	<b>Event Name.</b> NDBStartStarted <b>Event Type.</b> StartUp <b>Priority.</b> 1 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Started <i>version</i> <b>Description.</b> Data node <i>node_id</i> , running NDB version <i>version</i> , has started successfully.	<b>Event Name.</b> NDBStartCompleted <b>Event Type.</b> StartUp <b>Priority.</b> 1 <b>Severity.</b> INFO

<p><b>Log Message.</b> Node <i>node_id</i>: STTORY received after re-start finished</p> <p><b>Description.</b> The node has received a signal indicating that a cluster restart has completed.</p>	<p><b>Event Name.</b> STTORYRecieved</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 15</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: Start phase <i>phase</i> completed (<i>type</i>)</p> <p><b>Description.</b> The node has completed start phase <i>phase</i> of a <i>type</i> start. For a listing of start phases, see <a href="#">Section 16.5.1, “Summary of MySQL Cluster Start Phases”</a>. (<i>type</i> is one of <i>initial</i>, <i>system</i>, <i>node</i>, <i>initial node</i>, or <i>&lt;Unknown&gt;</i>.)</p>	<p><b>Event Name.</b> StartPhaseCompleted</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 4</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: CM_REGCONF president = <i>president_id</i>, own Node = <i>own_id</i>, our dynamic id = <i>dynamic_id</i></p> <p><b>Description.</b> Node <i>president_id</i> has been selected as “president”. <i>own_id</i> and <i>dynamic_id</i> should always be the same as the ID (<i>node_id</i>) of the reporting node.</p>	<p><b>Event Name.</b> CM_REGCONF</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 3</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: CM_REGREF from Node <i>president_id</i> to our Node <i>node_id</i>. Cause = <i>cause</i></p> <p><b>Description.</b> The reporting node (ID <i>node_id</i>) was unable to accept node <i>president_id</i> as president. The <i>cause</i> of the problem is given as one of <i>Busy</i>, <i>Election with wait = false</i>, <i>Not president</i>, <i>Election without selecting new candidate</i>, or <i>No such cause</i>.</p>	<p><b>Event Name.</b> CM_REGREF</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: We are Node <i>own_id</i> with dynamic ID <i>dynamic_id</i>, our left neighbour is Node <i>id_1</i>, our right is Node <i>id_2</i></p> <p><b>Description.</b> The node has discovered its neighboring nodes in the cluster (node <i>id_1</i> and node <i>id_2</i>). <i>node_id</i>, <i>own_id</i>, and <i>dynamic_id</i> should always be the same; if they are not, this indicates a serious misconfiguration of the cluster nodes.</p>	<p><b>Event Name.</b> FIND_NEIGHBOURS</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: <i>type</i> shutdown initiated</p> <p><b>Description.</b> The node has received a shutdown signal. The <i>type</i> of shutdown is either <i>Cluster</i> or <i>Node</i>.</p>	<p><b>Event Name.</b> NDBStopStarted</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 1</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: Node shutdown completed [, <i>action</i>] [Initiated by signal <i>signal</i>.]</p> <p><b>Description.</b> The node has been shut down. This report may include an <i>action</i>, which if present is one of <i>restarting</i>, <i>no start</i>, or <i>initial</i>. The report may also include a reference to an NDB Protocol <i>signal</i>; for possible signals, refer to <a href="#">Operations and Signals</a>.</p>	<p><b>Event Name.</b> NDBStopCompleted</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 1</p> <p><b>Severity.</b> INFO</p>
<p><b>Log Message.</b> Node <i>node_id</i>: Forced node shutdown completed [, <i>action</i>]. [Occured during startphase <i>start_phase</i>.] [ Initiated by <i>signal</i>.] [Caused by error <i>error_code</i>: '<i>error_message(error_classification)</i>'. <i>error_status</i>'. [(extra info <i>extra_code</i>)]</p>	<p><b>Event Name.</b> NDBStopForced</p> <p><b>Event Type.</b> StartUp</p> <p><b>Priority.</b> 1</p>

<p><b>Description.</b> The node has been forcibly shut down. The <i>action</i> (one of <i>re-starting</i>, <i>no start</i>, or <i>initial</i>) subsequently being taken, if any, is also reported. If the shutdown occurred while the node was starting, the report includes the <i>start_phase</i> during which the node failed. If this was a result of a <i>signal</i> sent to the node, this information is also provided (see <a href="#">Operations and Signals</a>, for more information). If the error causing the failure is known, this is also included; for more information about NDB error messages and classifications, see <a href="#">MySQL Cluster API Errors</a>.</p>	<p><b>Severity.</b> <a href="#">ALERT</a></p>
<p><b>Log Message.</b> Node <i>node_id</i>: Node shutdown aborted</p> <p><b>Description.</b> The node shutdown process was aborted by the user.</p>	<p><b>Event Name.</b> <a href="#">NDBStopAborted</a></p> <p><b>Event Type.</b> <a href="#">Startup</a></p> <p><b>Priority.</b> 1</p> <p><b>Severity.</b> <a href="#">INFO</a></p>
<p><b>Log Message.</b> Node <i>node_id</i>: StartLog: [GCI Keep: <i>keep_pos</i> LastCompleted: <i>last_pos</i> NewestRestorable: <i>restore_pos</i>]</p> <p><b>Description.</b> This reports global checkpoints referenced during a node start. The redo log prior to <i>keep_pos</i> is dropped. <i>last_pos</i> is the last global checkpoint in which data node the participated; <i>restore_pos</i> is the global checkpoint which is actually used to restore all data nodes.</p>	<p><b>Event Name.</b> <a href="#">StartREDOLog</a></p> <p><b>Event Type.</b> <a href="#">Startup</a></p> <p><b>Priority.</b> 4</p> <p><b>Severity.</b> <a href="#">INFO</a></p>
<p><b>Log Message.</b> <i>startup_message</i> [Listed separately; see below.]</p> <p><b>Description.</b> There are a number of possible startup messages that can be logged under different circumstances.</p>	<p><b>Event Name.</b> <a href="#">StartReport</a></p> <p><b>Event Type.</b> <a href="#">Startup</a></p> <p><b>Priority.</b> 4</p> <p><b>Severity.</b> <a href="#">INFO</a></p>
<p><b>Log Message.</b> Node <i>node_id</i>: Node restart completed copy of dictionary information</p> <p><b>Description.</b> Copying of data dictionary information to the restarted node has been completed.</p>	<p><b>Event Name.</b> <a href="#">NR_CopyDict</a></p> <p><b>Event Type.</b> <a href="#">NodeRestart</a></p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> <a href="#">INFO</a></p>
<p><b>Log Message.</b> Node <i>node_id</i>: Node restart completed copy of distribution information</p> <p><b>Description.</b> Copying of data distribution information to the restarted node has been completed.</p>	<p><b>Event Name.</b> <a href="#">NR_CopyDistr</a></p> <p><b>Event Type.</b> <a href="#">NodeRestart</a></p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> <a href="#">INFO</a></p>
<p><b>Log Message.</b> Node <i>node_id</i>: Node restart starting to copy the fragments to Node <i>node_id</i></p> <p><b>Description.</b> Copy of fragments to starting data node <i>node_id</i> has begun</p>	<p><b>Event Name.</b> <a href="#">NR_CopyFragStarted</a></p> <p><b>Event Type.</b> <a href="#">NodeRestart</a></p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> <a href="#">INFO</a></p>
<p><b>Log Message.</b> Node <i>node_id</i>: Table ID = <i>table_id</i>, fragment ID = <i>fragment_id</i> have been copied to Node <i>node_id</i></p> <p><b>Description.</b> Fragment <i>fragment_id</i> from table <i>table_id</i> has been</p>	<p><b>Event Name.</b> <a href="#">NR_CopyFragDone</a></p> <p><b>Event Type.</b> <a href="#">NodeRestart</a></p>

copied to data node <i>node_id</i>	<b>Priority.</b> 10 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Node restart completed copying the fragments to Node <i>node_id</i> <b>Description.</b> Copying of all table fragments to restarting data node <i>node_id</i> has been completed	<b>Event Name.</b> NR_CopyFrgsCompleted <b>Event Type.</b> NodeRestart <b>Priority.</b> 8 <b>Severity.</b> INFO
<b>Log Message.</b> Any of the following: <ol style="list-style-type: none"> <li>Node <i>node_id</i>: Node <i>node1_id</i> completed failure of Node <i>node2_id</i></li> <li>All nodes completed failure of Node <i>node_id</i></li> <li>Node failure of <i>node_id</i>block completed</li> </ol> <b>Description.</b> One of the following (each corresponding to the same-numbered message listed above): <ol style="list-style-type: none"> <li>Data node <i>node1_id</i> has detected the failure of data node <i>node2_id</i></li> <li>All (remaining) data nodes have detected the failure of data node <i>node_id</i></li> <li>The failure of data node <i>node_id</i> has been detected in the <i>block</i>NDB kernel block, where block is 1 of DBTC, DBDICT, DBDIH, or DBLQH; for more information, see <a href="#">NDB Kernel Blocks</a></li> </ol>	<b>Event Name.</b> NodeFailCompleted <b>Event Type.</b> NodeRestart <b>Priority.</b> 8 <b>Severity.</b> ALERT
<b>Log Message.</b> Node <i>mgm_node_id</i> : Node <i>data_node_id</i> has failed. The Node state at failure was <i>state_code</i> <b>Description.</b> A data node has failed. Its state at the time of failure is described by an arbitration state code <i>state_code</i> : possible state code values can be found in the file <code>include/kernel/signaldata/ArbitSignalData.hpp</code> .	<b>Event Name.</b> NODE_FAILREP <b>Event Type.</b> NodeRestart <b>Priority.</b> 8 <b>Severity.</b> ALERT
<b>Log Message.</b> President restarts arbitration thread [ <i>state=state_code</i> ] or Prepare arbitrator node <i>node_id</i> [ <i>ticket=ticket_id</i> ] or Receive arbitrator node <i>node_id</i> [ <i>ticket=ticket_id</i> ] or Started arbitrator node <i>node_id</i> [ <i>ticket=ticket_id</i> ] or Lost arbitrator node <i>node_id</i> - process failure [ <i>state=state_code</i> ] or Lost arbitrator node <i>node_id</i> - process exit [ <i>state=state_code</i> ] or Lost arbitrator node <i>node_id</i> - <i>error_message</i> [ <i>state=state_code</i> ] <b>Description.</b> This is a report on the current state and progress of arbitration in the cluster. <i>node_id</i> is the node ID of the management node or SQL node selected as the arbitrator. <i>state_code</i> is an arbitration state code, as found in <code>include/kernel/signaldata/ArbitSignalData.hpp</code> . When an error has occurred, an <i>error_message</i> , also defined in <code>ArbitSignalData.hpp</code> , is provided. <i>ticket_id</i> is a unique identifier handed out by the arbitrator when it is selected to all the nodes that participated in its selection; this is used to ensure that each node requesting arbitration was one of the nodes	<b>Event Name.</b> ArbitState <b>Event Type.</b> NodeRestart <b>Priority.</b> 6 <b>Severity.</b> INFO

that took part in the selection process.	
<p><b>Log Message.</b> Arbitration check lost - less than 1/2 nodes left or Arbitration check won - all node groups and more than 1/2 nodes left or Arbitration check won - node group majority or Arbitration check lost - missing node group or Network partitioning - arbitration required or Arbitration won - positive reply from node <i>node_id</i> or Arbitration lost - negative reply from node <i>node_id</i> or Network partitioning - no arbitrator available or Network partitioning - no arbitrator configured or Arbitration failure - <i>error_message</i> [<i>state=state_code</i>]</p> <p><b>Description.</b> This message reports on the result of arbitration. In the event of arbitration failure, an <i>error_message</i> and an arbitration <i>state_code</i> are provided; definitions for both of these are found in <code>include/kernel/signaldata/ArbitSignalData.hpp</code>.</p>	<p><b>Event Name.</b> <code>ArbitResult</code></p> <p><b>Event Type.</b> <code>NodeRestart</code></p> <p><b>Priority.</b> 2</p> <p><b>Severity.</b> <code>ALERT</code></p>
<p><b>Log Message.</b> Node <i>node_id</i>: GCP Take over started</p> <p><b>Description.</b> This node is attempting to assume responsibility for the next global checkpoint (that is, it is becoming the master node)</p>	<p><b>Event Name.</b> <code>GCP_TakeoverStarted</code></p> <p><b>Event Type.</b> <code>NodeRestart</code></p> <p><b>Priority.</b> 7</p> <p><b>Severity.</b> <code>INFO</code></p>

### 16.5.6.2. MySQL Cluster: [NDB](#) Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

Error Code	Error Name	Error Text
0x00	<a href="#">TE_NO_ERROR</a>	NO ERROR
0x01	<a href="#">TE_ERROR_CLOSING_SOCKET</a>	ERROR FOUND DURING CLOSING OF SOCKET
0x02	<a href="#">TE_ERROR_IN_SELECT_BEFORE_ACCEPT</a>	ERROR FOUND BEFORE ACCEPT. THE TRANSPORTER WILL RETRY
0x03	<a href="#">TE_INVALID_MESSAGE_LENGTH</a>	ERROR FOUND IN MESSAGE (INVALID MESSAGE LENGTH)
0x04	<a href="#">TE_INVALID_CHECKSUM</a>	ERROR FOUND IN MESSAGE (CHECKSUM)
0x05	<a href="#">TE_COULD_NOT_CREATE_SOCKET</a>	ERROR FOUND WHILE CREATING SOCKET(CAN'T CREATE SOCKET)
0x06	<a href="#">TE_COULD_NOT_BIND_SOCKET</a>	ERROR FOUND WHILE BINDING SERVER SOCKET
0x07	<a href="#">TE_LISTEN_FAILED</a>	ERROR FOUND WHILE LISTENING TO SERVER SOCKET
0x08	<a href="#">TE_ACCEPT_RETURN_ERROR</a>	ERROR FOUND DURING ACCEPT(ACCEPT RETURN ERROR)
0x0b	<a href="#">TE_SHM_DISCONNECT</a>	THE REMOTE NODE HAS DISCONNECTED
0x0c	<a href="#">TE_SHM_IPC_STAT</a>	UNABLE TO CHECK SHM SEGMENT
0x0d	<a href="#">TE_SHM_UNABLE_TO_CREATE_SEGMENT</a>	UNABLE TO CREATE SHM SEGMENT
0x0e	<a href="#">TE_SHM_UNABLE_TO_ATTACH_SEGMENT</a>	UNABLE TO ATTACH SHM SEGMENT
0x0f	<a href="#">TE_SHM_UNABLE_TO_REMOVE_SEGMENT</a>	UNABLE TO REMOVE SHM SEGMENT
0x10	<a href="#">TE_TOO_SMALL_SIGID</a>	SIG ID TOO SMALL
0x11	<a href="#">TE_TOO_LARGE_SIGID</a>	SIG ID TOO LARGE
0x12	<a href="#">TE_WAIT_STACK_FULL</a>	WAIT STACK WAS FULL
0x13	<a href="#">TE_RECEIVE_BUFFER_FULL</a>	RECEIVE BUFFER WAS FULL
0x14	<a href="#">TE_SIGNAL_LOST_SEND_BUFFER_FULL</a>	SEND BUFFER WAS FULL, AND TRYING

Error Code	Error Name	Error Text
		TO FORCE SEND FAILS
0x15	TE_SIGNAL_LOST	SEND FAILED FOR UNKNOWN REASON(SIGNAL LOST)
0x16	TE_SEND_BUFFER_FULL	THE SEND BUFFER WAS FULL, BUT SLEEPING FOR A WHILE SOLVED
0x0017	TE_SCI_LINK_ERROR	THERE IS NO LINK FROM THIS NODE TO THE SWITCH
0x18	TE_SCI_UNABLE_TO_START_SEQUENCE	COULD NOT START A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXHAUSTED OR NO SEQUENCE HAS BEEN CREATED
0x19	TE_SCI_UNABLE_TO_REMOVE_SEQUENCE	COULD NOT REMOVE A SEQUENCE
0x1a	TE_SCI_UNABLE_TO_CREATE_SEQUENCE	COULD NOT CREATE A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXHAUSTED. MUST REBOOT
0x1b	TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR	TRIED TO SEND DATA ON REDUNDANT LINK BUT FAILED
0x1c	TE_SCI_CANNOT_INIT_LOCALSEGMENT	CANNOT INITIALIZE LOCAL SEGMENT
0x1d	TE_SCI_CANNOT_MAP_REMOTESEGMENT	CANNOT MAP REMOTE SEGMENT
0x1e	TE_SCI_UNABLE_TO_UNMAP_SEGMENT	CANNOT FREE THE RESOURCES USED BY THIS SEGMENT (STEP 1)
0x1f	TE_SCI_UNABLE_TO_REMOVE_SEGMENT	CANNOT FREE THE RESOURCES USED BY THIS SEGMENT (STEP 2)
0x20	TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT	CANNOT DISCONNECT FROM A REMOTE SEGMENT
0x21	TE_SHM_IPC_PERMANENT	SHM IPC PERMANENT ERROR
0x22	TE_SCI_UNABLE_TO_CLOSE_CHANNEL	UNABLE TO CLOSE THE SCI CHANNEL AND THE RESOURCES ALLOCATED

## 16.5.7. MySQL Cluster Single User Mode

*Single user mode* enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see [Section 16.5.9.8, “The ndbinfo nodes Table”](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

### Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes
- Method 2:
 

Restart database nodes prior to entering single user mode.

## 16.5.8. Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

See [Section 12.7.5.16, “SHOW ENGINE Syntax”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 12.7.5.17, “SHOW ENGINES Syntax”](#), for more detailed information.

### Note

In MySQL 5.1 and later, this statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES`, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
+-----+
| support |
+-----+
| ENABLED |
+-----+
```

See [Section 19.6, “The INFORMATION\\_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the NDB storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
```

Variable_name	Value
ndb_autoincrement_prefetch_sz	32
ndb_cache_check_time	0
ndb_extra_logging	0
ndb_force_send	ON
ndb_index_stat_cache_entries	32
ndb_index_stat_enable	OFF
ndb_index_stat_update_freq	20
ndb_report_thresh_binlog_epoch_slip	3
ndb_report_thresh_binlog_mem_usage	10
ndb_use_copying_alter_table	OFF
ndb_use_exact_count	ON
ndb_use_transactions	ON

See [Section 5.1.3, “Server System Variables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME LIKE 'NDB%';
```

VARIABLE_NAME	VARIABLE_VALUE
NDB_AUTOINCREMENT_PREFETCH_SZ	32
NDB_CACHE_CHECK_TIME	0
NDB_EXTRA_LOGGING	0
NDB_FORCE_SEND	ON
NDB_INDEX_STAT_CACHE_ENTRIES	32
NDB_INDEX_STAT_ENABLE	OFF
NDB_INDEX_STAT_UPDATE_FREQ	20
NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP	3
NDB_REPORT_THRESH_BINLOG_MEM_USAGE	10
NDB_USE_COPYING_ALTER_TABLE	OFF
NDB_USE_EXACT_COUNT	ON
NDB_USE_TRANSACTIONS	ON

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
-> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME = 'ndb_force_send';
```

VARIABLE_VALUE
ON

See [Section 19.10, “The INFORMATION\\_SCHEMA GLOBAL\\_VARIABLES and SESSION\\_VARIABLES Tables”](#), and [Section 5.1.3, “Server System Variables”](#), for more information.

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

Variable_name	Value
Ndb_cluster_node_id	10
Ndb_config_from_host	192.168.0.103
Ndb_config_from_port	1186
Ndb_number_of_data_nodes	4

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

Variable_name	Value
Ndb_cluster_node_id	0
Ndb_config_from_host	
Ndb_config_from_port	0
Ndb_number_of_data_nodes	0

See also [Section 12.7.5.36, “SHOW STATUS Syntax”](#).

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement provides similar output to the `SHOW` command discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See [Section 19.9, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#), for more information.

You can also query the tables in the `ndbinfo` information database for real-time data about many MySQL Cluster operations. See [Section 16.5.9, “The ndbinfo MySQL Cluster Information Database”](#).

## 16.5.9. The `ndbinfo` MySQL Cluster Information Database

`ndbinfo` is a database storing containing information specific to MySQL Cluster.

This database contains a number of tables, each providing a different sort of data about MySQL Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with MySQL Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	GPL
partition	ACTIVE	STORAGE ENGINE	NULL	GPL
ARCHIVE	ACTIVE	STORAGE ENGINE	NULL	GPL
BLACKHOLE	ACTIVE	STORAGE ENGINE	NULL	GPL
CSV	ACTIVE	STORAGE ENGINE	NULL	GPL
FEDERATED	DISABLED	STORAGE ENGINE	NULL	GPL
MEMORY	ACTIVE	STORAGE ENGINE	NULL	GPL
InnoDB	ACTIVE	STORAGE ENGINE	NULL	GPL
MyISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
MRG_MYISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
ndbcluster	ACTIVE	STORAGE ENGINE	NULL	GPL
<b>ndbinfo</b>	<b>ACTIVE</b>	<b>STORAGE ENGINE</b>	<b>NULL</b>	<b>GPL</b>

12 rows in set (0.00 sec)

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```
mysql> SHOW ENGINES;
```

Engine	Support	Comment	Transactions	XA	Savepoints
ndbcluster	YES	Clustered, fault-tolerant tables	YES	NO	NO
MRG_MYISAM	YES	Collection of identical MyISAM tables	NO	NO	NO
<b>ndbinfo</b>	<b>YES</b>	<b>MySQL Cluster system information storage engine</b>	<b>NO</b>	<b>NO</b>	<b>NO</b>
CSV	YES	CSV storage engine	NO	NO	NO
MEMORY	YES	Hash based, stored in memory, useful for temporary tables	NO	NO	NO
FEDERATED	NO	Federated MySQL storage engine	NULL	NULL	NULL
ARCHIVE	YES	Archive storage engine	NO	NO	NO
InnoDB	YES	Supports transactions, row-level locking, and foreign keys	YES	YES	YES
MyISAM	DEFAULT	Default engine as of MySQL 3.23 with great performance	NO	NO	NO
BLACKHOLE	YES	/dev/null storage engine (anything you write to it disappears)	NO	NO	NO

```
10 rows in set (0.00 sec)
```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| ndbinfo |
| test |
+-----+
4 rows in set (0.00 sec)
```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to a MySQL Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'CONNECTION TO NDB FAILED' FROM NDBINFO`.

### Note

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not visible to the MySQL Server.

All `ndbinfo` tables are read-only.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+-----+
| Tables_in_ndbinfo |
+-----+
| blocks |
| config_params |
| counters |
| diskpagebuffer |
| logbuffers |
| logspaces |
| memoryusage |
| nodes |
| resources |
| transporters |
+-----+
9 rows in set (0.00 sec)
```

You can execute `SELECT` statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+-----+-----+-----+-----+
| node_id | DATA_MEMORY | used | max |
+-----+-----+-----+-----+
| 1 | DATA_MEMORY | 3230 | 6408 |
| 2 | DATA_MEMORY | 3230 | 6408 |
| 1 | INDEX_MEMORY | 16 | 12832 |
| 2 | INDEX_MEMORY | 16 | 12832 |
+-----+-----+-----+-----+
4 rows in set (0.37 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
> FROM memoryusage
> WHERE DATA_MEMORY = 'DATA_MEMORY';
+-----+
| Data Memory Used, All Nodes |
+-----+
| 6460 |
+-----+
```

```

1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
>       FROM memoryusage
>       WHERE DATA_MEMORY = 'INDEX_MEMORY';
+-----+
| Total IndexMemory Available |
+-----+
|                25664       |
+-----+
1 row in set (0.33 sec)

```

`ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lower-case. Trying to use the wrong lettercase results in an error, as shown in this example:

```

mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
|      1  |  13602 | STARTED |            0 |
|      2  |    16  | STARTED |            0 |
+-----+-----+-----+-----+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): TABLE 'NDBINFO.Nodes' DOESN'T EXIST

```

### Important

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

#### 16.5.9.1. The `ndbinfo blocks` Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see [NDB Kernel Blocks](#)). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the `blocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>block_number</code>	integer	Block number
<code>block_name</code>	string	Block name

Although this is a static table, its content could possibly vary between different MySQL Cluster releases.

#### 16.5.9.2. The `ndbinfo config_params` Table

The `config_params` table is a static table which provides the names and internal ID numbers of all MySQL Cluster configuration parameters.

The following table provides information about the columns in the `config_params` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>param_number</code>	integer	The parameter's internal ID number
<code>param_name</code>	string	The name of the parameter

Although this is a static table, its content can vary between MySQL Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

#### 16.5.9.3. The `ndbinfo counters` Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are

kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The data node ID
<code>block_name</code>	string	Name of the associated NDB kernel block (see <a href="#">NDB Kernel Blocks</a> ).
<code>block_instance</code>	integer	<code>_REMARK_</code>
<code>counter_id</code>	integer	The counter's internal ID number; normally an integer between 1 and 10, inclusive.
<code>counter_name</code>	string	The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.
<code>val</code>	integer	The counter's value

Each counter is associated with a particular NDB kernel block. Prior to MySQL Cluster NDB 7.2.0, this was limited to either the `DBLQH` kernel block or the `DBTC` kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see [The DBLQH Block](#)).

The `ATTRINFO`, `TRANSACTIONS`, `COMMITTS`, `READS`, `SIMPLE_READS`, `WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the `DBTC` (transaction co-ordinator) kernel block (see [The DBTC Block](#)).

MySQL Cluster NDB 7.2.0, as part of its implementation of distributed pushed-down joins, adds the `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`, `READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters. These counters are associated with the `DBSPJ` (select push-down join) kernel block (see [The DBSPJ Block](#)).

#### 16.5.9.4. The `ndbinfo diskpagebuffer` Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by MySQL Cluster Disk Data tables.

The following table provides information about the columns in the `diskpagebuffer` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The data node ID
<code>block_instance</code>	integer	<code>_REMARK_</code>
<code>pages_written</code>	integer	Number of pages written to disk.
<code>pages_written_lcp</code>	integer	Number of pages written by local checkpoints.
<code>pages_read</code>	integer	Number of pages read from disk
<code>log_waits</code>	integer	Number of page writes waiting for log to be written to disk
<code>page_requests_direct_return</code>	integer	Number of requests for pages that were available in buffer
<code>page_requests_wait_queue</code>	integer	Number of requests that had to wait for pages to become available in buffer
<code>page_requests_wait_io</code>	integer	Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

You can use this table with MySQL Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
    AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+-----+-----+
| node_id | hit_ratio |
+-----+-----+
|      5 | 97.6744  |
|      6 | 97.6879  |
|      7 | 98.1776  |
|      8 | 98.1343  |
+-----+-----+
4 rows in set (0.00 sec)
```

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

### Note

A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

## 16.5.9.5. The `ndbinfo logbuffers` Table

The `logbuffer` table provides information on MySQL Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Remarks
<code>node_id</code>	integer	The ID of this data node.
<code>log_type</code>	string	Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> .
<code>log_id</code>	integer	The log ID.
<code>log_part</code>	integer	The log part number.
<code>total</code>	integer	Total space available for this log.
<code>used</code>	integer	Space used by this log.

## 16.5.9.6. The `ndbinfo logspaces` Table

This table provides information about MySQL Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Remarks
<code>node_id</code>	integer	The ID of this data node.
<code>log_type</code>	string	Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> .
<code>log_id</code>	integer	The log ID.
<code>log_part</code>	integer	The log part number.
<code>total</code>	integer	Total space available for this log.
<code>used</code>	integer	Space used by this log.

### 16.5.9.7. The `ndbinfo memoryusage` Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The following table provides information about the columns in the `memoryusage` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The node ID of this data node.
<code>memory_type</code>	string	One of <code>DATA_MEMORY</code> or <code>INDEX_MEMORY</code> .
<code>used</code>	integer	Number of bytes currently used for data memory or index memory by this data node.
<code>used_pages</code>	integer	Number of pages currently used for data memory or index memory by this data node; see text.
<code>total</code>	integer	Total number of bytes of data memory or index memory available for this data node; see text.
<code>total_pages</code>	integer	Total number of memory pages available for data memory or index memory on this data node; see text.

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 1 and 2, and the `config.ini` file contains the following:

```
[nbd default]
DataMemory = 100M
IndexMemory = 100M
```

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
+-----+-----+-----+
| node_id | memory_type | total |
+-----+-----+-----+
| 1       | Data memory | 104857600 |
| 1       | Index memory | 105119744 |
| 2       | Data memory | 104857600 |
| 2       | Index memory | 105119744 |
+-----+-----+-----+
4 rows in set (0.30 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`.

### 16.5.9.8. The `ndbinfo nodes` Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The data node's unique node ID in the cluster.
<code>uptime</code>	integer	Time since the node was last started, in seconds.
<code>status</code>	string	Current status of the data node; see text for possible values.

Column Name	Type	Remarks
<code>start_phase</code>	integer	If the data node is starting, the current start phase.
<code>config_generation</code>	integer	The version of the cluster configuration file in use on this data node.

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtid` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a non-zero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see [Section 16.5.7, “MySQL Cluster Single User Mode”](#)). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see [Section 16.5.2, “Commands in the MySQL Cluster Management Client”](#)). If the node is not currently starting, then this column shows 0. For a listing of MySQL Cluster start phases with descriptions, see [Section 16.5.1, “Summary of MySQL Cluster Start Phases”](#).

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
```

node_id	uptime	status	start_phase	config_generation
1	10462	STARTED	0	6
2	10460	STARTED	0	6
3	10457	STARTED	0	5
4	10455	STARTED	0	6

```
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have a MySQL Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
```

node_id	uptime	status	start_phase	config_generation
1	11776	STARTED	0	6
2	11774	STARTED	0	6
3	11771	STARTED	0	6
4	11769	STARTED	0	6

```
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
```

node_id	uptime	status	start_phase	config_generation
---------	--------	--------	-------------	-------------------

1	11807	STARTED	0	6
3	11802	STARTED	0	6
4	11800	STARTED	0	6

3 rows in set (0.02 sec)

### 16.5.9.9. The `ndbinfo resources` Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the `resources` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The unique node ID of this data node.
<code>resource_name</code>	string	Name of the resource; see text.
<code>reserved</code>	integer	The amount reserved for this resource.
<code>used</code>	integer	The amount actually used by this resource.
<code>max</code>	integer	The maximum amount of this resource used, since the node was last started.

The `resource_name` can be one of `RESERVED`, `DISK_OPERATIONS`, `DISK_RECORDS`, `DATA_MEMORY`, `JOBBUFFER`, `FILE_BUFFERS`, or `TRANSPORTER_BUFFERS`.

### 16.5.9.10. The `ndbinfo transporters` Table

This table contains information about NDB transporters.

The following table provides information about the columns in the `transporters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	This data node's unique node ID in the cluster.
<code>remote_node_id</code>	integer	The remote data node's node ID.
<code>status</code>	string	Status of the connection.

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data nodes which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.100.10.1 (mysql-5.1.41 ndb-7.1.1, Nodegroup: 0, Master)
id=2 @10.100.10.2 (mysql-5.1.41 ndb-7.1.1, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @10.100.10.10 (mysql-5.1.41 ndb-7.1.1)

[mysqld(API)] 2 node(s)
id=20 @10.100.10.20 (mysql-5.1.41 ndb-7.1.1)
id=21 @10.100.10.21 (mysql-5.1.41 ndb-7.1.1)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT * FROM transporters;
```

node_id	remote_node_id	status
1	1	CONNECTED
1	2	CONNECTED
1	10	CONNECTED
1	20	CONNECTED
1	21	CONNECTED
2	1	CONNECTED
2	2	CONNECTED
2	10	CONNECTED
2	20	CONNECTED
2	21	CONNECTED

```
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the `ndb_mgm` client `STOP` command, then repeat the query, this table now shows only 5 rows—1 row for each connection from the remaining data node to another node, including both itself and the data node that is currently offline, as shown here:

```
mysql> SELECT * FROM transporters;
```

node_id	remote_node_id	status
1	1	CONNECTED
1	2	CONNECTED
1	10	CONNECTED
1	20	CONNECTED
1	21	CONNECTED

```
5 rows in set (0.02 sec)
```

## 16.5.10. MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics covered in this section include the following:

- MySQL Cluster and network security issues
- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to MySQL Cluster

### 16.5.10.1. MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including

SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 16.5.10.2, “MySQL Cluster and MySQL Privileges”](#), for more information about this and related issues.)

### Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available [elsewhere in this chapter](#) about the `HostName` parameter. Also see [Section 16.3.1, “Quick Test Setup of MySQL Cluster”](#), for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of a MySQL Cluster setup using such a physically segregated network here:

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-*

*based firewall.*

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

### Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 5.3.3, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for MySQL Cluster is illustrated here:

Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

Type of Node to be Accessed	Traffic to Permit
SQL or API node	<ul style="list-style-type: none"><li>• It originates from the IP address of a management or data node (using any TCP or UDP port).</li><li>• It originates from within the network in which the cluster resides and is on the port that your application is using.</li></ul>
Data node or Management node	<ul style="list-style-type: none"><li>• It originates from the IP address of a management or data node (using any TCP or UDP port).</li><li>• It originates from the IP address of an SQL or API node.</li></ul>

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. [iptables](#) is a very common and reliable firewall application, which is often used with [APF](#) as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

#### Note

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

### 16.5.10.2. MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types ([SELECT](#) privilege, [UPDATE](#) privilege, [DELETE](#) privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on [NDB](#) tables, databases containing such tables, and columns within such tables are identical in all respects with the [GRANT](#) and [REVOKE](#) statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the [CREATE USER](#) and [DROP USER](#) statements.

It is important to keep in mind that, by default, the MySQL grant tables use the [MyISAM](#) storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. In MySQL Cluster NDB 7.2 (and later), you can enable automatic distribution of MySQL users and privileges across MySQL Cluster SQL nodes; see [Section 16.5.13, “Distributed MySQL Privileges for MySQL Cluster”](#), for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for [NDB](#) tables on one SQL node from users that have privileges on another SQL node; this is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the MySQL Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.
- There is no firewall, or the firewall fails to protect against access to the MySQL Cluster from hosts external to the network.
- The host name or IP address of the MySQL Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster` `--ndb-connectstring=management_host` and access this MySQL Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all [NDB](#) databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all [NDB](#) tables in a given database
- Run any legal MySQL statements on any of the discovered tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table
  - `DELETE FROM some_table` to delete all the data from a table
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  - `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than [NDB](#), and so not visible to a “rogue” SQL node.

A user who can log in as `root` can also access the [INFORMATION\\_SCHEMA](#) database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in [INFORMATION\\_SCHEMA](#).

It is also a very good idea to use different passwords for the `root` accounts on different MySQL Cluster SQL nodes unless you are

using distributed privileges.

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

### Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.2, you should never convert the system tables in the `mysql` database to use the `NDB` storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect `mysql` tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than `MyISAM`.* This is a consequence of various MySQL Server internals. Beginning with MySQL Cluster NDB 7.2, you can use a stored procedure provided for this purpose (see [Section 16.5.13, “Distributed MySQL Privileges for MySQL Cluster”](#)), but you are strongly advised not to attempt convert the system tables manually.

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.
2. You can cause MySQL users and privileges to be distributed automatically among SQL nodes using the SQL script, and the stored procedures which it contains, that are supplied for this purpose.
3. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in a MySQL Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

## 16.5.10.3. MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql` system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the system user `mysql` by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root      10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql     10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
/usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
--datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
--ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
--log-error=/usr/local/mysql/var/mothra.err
jon       10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

### Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by

■ MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see [Section 16.5.10.2, “MySQL Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root

mysql> UPDATE mysql.user
->     SET Password=PASSWORD('secure_password')
->     WHERE User='root';

mysql> DELETE FROM mysql.user
->     WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

### Note

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 16.4, “MySQL Cluster Programs”](#), for more information about these utilities.

## 16.5.11. MySQL Cluster Disk Data Tables

It is possible to store the nonindexed columns of `NDB` tables on disk, rather than in RAM.

As part of implementing MySQL Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronising a starting node with very large data sets. For more information, see the paper [Recovery Principles of MySQL Cluster 5.1](#), by MySQL Cluster developers Mikael Ronström and Jonas Orelund.

MySQL Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [MySQL Cluster Disk Data configuration parameters](#) and [MySQL Cluster Disk Data storage and GCP STOP errors](#).

The performance of a MySQL Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see [Section 16.5.11.2, “Using Symbolic Links with Disk Data Objects”](#).

### 16.5.11.1. MySQL Cluster Disk Data Objects

MySQL Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.
- *Undo log files* undo information required for rolling back transactions.
- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.
- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the MySQL Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

MySQL Cluster tablespaces and log file groups are not implemented as files.

## Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `ddl`.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes), the basic steps for creating a MySQL Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undo file*).

## Note

Undo log files are necessary only for Disk Data tables; they are not used for `NDBCLUSTER` tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognisable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` clause. In MySQL Cluster NDB 7.2, the only permitted values for this clause are `NDBCLUSTER` and `NDB`.

## Important

There can exist at most one log file group in the same MySQL Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
- For more information about the `CREATE LOGFILE GROUP` statement, see [Section 12.1.14, “CREATE LOGFILE GROUP Syntax”](#). For more information about `ALTER LOGFILE GROUP`, see [Section 12.1.3, “ALTER LOGFILE GROUP Syntax”](#).

- Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.
  - When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
  - All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL MySQL Cluster NDB 7.2, the only permitted values for this clause are `NDBCLUSTER` and `NDB`.
  - For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), and [Section 12.1.8, “ALTER TABLESPACE Syntax”](#).
- Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

### Note

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 12.1.17, “CREATE TABLE Syntax”](#), for more information.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are in-

dexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL Cluster NDB 7.2, only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see [Section 16.5.11.2, “Using Symbolic Links with Disk Data Objects”](#), for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
-> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
-> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE . . . DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra “NULL row” provides additional information about undo log files. For more information and examples, see [Section 19.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

It is also possible to view information about allocated and free disk space for each Disk Data table or table partition using the `ndb_desc` utility. For more information, see [Section 16.4.9, “ndb\\_desc — Describe NDB Tables”](#).

### 16.5.11.2. Using Symbolic Links with Disk Data Objects

The performance of a MySQL Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. In early versions of MySQL Cluster, there was no direct support for this in MySQL Cluster, but it was possible to achieve this separation using symbolic links as described in this section. MySQL Cluster NDB 7.2 supports the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`, which make the use of symbolic links for this purpose unnecessary. For more information about these parameters, see [Disk Data file system parameters](#).

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
```

```
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

### Note

In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute your operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

```
shell> cd /data0/ndb_2_fs
shell> ls
D1 D10 D11 D2 D8 D9 LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata
```

You should now have two symbolic links:

```
shell> ls -l --hide=D*
lrwxrwxrwx 1 user group 30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group 30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'dnlogs/undo1.log'
-> INITIAL_SIZE 150M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'dndata/data1.log'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 1G
-> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using `/data0` for both data node file systems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do something similar to what is shown here:

```
shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ln -s /data1/dn3 ndb_3_fs/dd
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn3
```

- Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'dd/undo1.log'
-> INITIAL_SIZE 150M
```

```

-> UNDO_BUFFER_SIZE = 1M
-> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'dd/data1.log'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 1G
-> ENGINE=NDBCLUSTER;

```

Verify that the files were created and placed correctly as shown here:

```

shell> cd /data1
shell> ls
dn2          dn3
shell> ls dn2
undo1.log    data1.log
shell> ls dn3
undo1.log    data1.log

```

### 16.5.11.3. MySQL Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 10.5, “Data Type Storage Requirements”](#).

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 19.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

#### Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

#### Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

## 16.5.12. Adding MySQL Cluster Data Nodes Online

This section describes how to add MySQL Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

#### Important

Currently, you must add new data nodes to a MySQL Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

### 16.5.12.1. Adding MySQL Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding MySQL Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed) or `BLOB` table data.

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using MySQL Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

**Failure handling.** Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Failure occurs during:	Failure occurs in:		
	“Old” data nodes	“New” data nodes	System
Node group creation	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The creation of the node group is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The creation of the node group is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the execution of <code>CREATE NODEGROUP</code> has reached the internal commit point:</b> When restarted, the cluster includes the new node group. Otherwise it without.</li> <li>• <b>If the execution of <code>CREATE NODEGROUP</code> has not yet reached the internal commit point:</b> When restarted, the cluster does not include the new node group.</li> </ul>
Table reorganization	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the execution of an <code>ALTER ONLINE TABLE table REORGANIZE PARTITION</code> statement has reached the internal commit point:</b> When the cluster is restarted, the data and indexes belonging to <code>table</code> are distributed using the “new” data nodes.</li> <li>• <b>If the execution of an <code>ALTER ONLINE TABLE table REORGANIZE PARTITION</code> statement has not yet reached the internal commit point:</b> When the</li> </ul>

Failure occurs during:	Failure occurs in:		
	“Old” data nodes	“New” data nodes	System
			cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes.

**Dropping node groups.** The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

### 16.5.12.2. Adding MySQL Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to a MySQL Cluster. This procedure applies whether you are using `ndbd` or `ndbmt` binaries for the data node processes. For a more detailed example, see [Section 16.5.12.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”](#).

Assuming that you already have a running MySQL Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all MySQL Cluster management servers.

#### Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing MySQL Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the MySQL Cluster.
5. Perform an initial start of the new data nodes.

#### Note

The new data nodes may be started in any order, and can also be started concurrently, as long as they are started after the rolling restarts of all existing nodes have been completed and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the MySQL Cluster management client to create the new node group or

node groups to which the new data nodes will belong.

7. Redistribute the cluster's data among all data nodes (including the new ones) by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

### Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized using `ALTER ONLINE TABLE tbl REORGANIZE PARTITION`.

8. Reclaim the space freed on the “old” nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

## 16.5.12.3. Adding MySQL Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new MySQL Cluster data nodes online, starting with a MySQL Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.** For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

### Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.61-ndb-7.1.20, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.61-ndb-7.1.20, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.61-ndb-7.1.20)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.61-ndb-7.1.20)
```

```
id=21 @192.168.0.21 (5.1.61-ndb-7.1.20)
```

Finally, we assume that the cluster contains a single **NDBCLUSTER** table created as shown here:

```
USE n;

CREATE TABLE ips (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  country_code CHAR(2) NOT NULL,
  type CHAR(4) NOT NULL,
  ip_address varchar(15) NOT NULL,
  addresses BIGINT UNSIGNED DEFAULT NULL,
  date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

### Note

In this example, we show the single-threaded **ndbd** being used for the data node processes. However—beginning with MySQL Cluster NDB 7.0.4—you can also apply this example, if you are using the multi-threaded **ndbmt** by substituting **ndbmt** for **ndbd** wherever it appears in the steps that follow. (Bug #43108)

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add **[ndbd]** sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the **config.ini** file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2
[ndbd]
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client **STOP** command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown
shell>
```

- Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO      -- NDB Cluster Management Server. 5.1.61-ndb-7.1.20
2008-12-08 17:29:23 [MgmSrvr] INFO      -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1   @192.168.0.1 (5.1.61-ndb-7.1.20, Nodegroup: 0, Master)
id=2   @192.168.0.2 (5.1.61-ndb-7.1.20, Nodegroup: 0)
id=3   (not connected, accepting connect from 192.168.0.3)
id=4   (not connected, accepting connect from 192.168.0.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10  @192.168.0.10 (5.1.61-ndb-7.1.20)

[mysqld(API)] 2 node(s)
id=20  @192.168.0.20 (5.1.61-ndb-7.1.20)
id=21  @192.168.0.21 (5.1.61-ndb-7.1.20)
```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.1.20)
Node 1: Started (version 7.1.20)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.1.20)
Node 2: Started (version 7.1.20)
```

### Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose

to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 192.168.0.10 --initial
```

### Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step.* Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.61-ndb-7.1.20, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.61-ndb-7.1.20, Nodegroup: 0)
id=3 @192.168.0.3 (5.1.61-ndb-7.1.20, no nodegroup)
id=4 @192.168.0.4 (5.1.61-ndb-7.1.20, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.61-ndb-7.1.20)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.61-ndb-7.1.20)
id=21 @192.168.0.21 (5.1.61-ndb-7.1.20)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.61-ndb-7.1.20, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.61-ndb-7.1.20, Nodegroup: 0)
id=3 @192.168.0.3 (5.1.61-ndb-7.1.20, Nodegroup: 1)
id=4 @192.168.0.4 (5.1.61-ndb-7.1.20, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.61-ndb-7.1.20)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.61-ndb-7.1.20)
id=21 @192.168.0.21 (5.1.61-ndb-7.1.20)
```

**Step 7: Redistribute cluster data.** When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still

uses only 2 partitions (in the **Per partition info** section of the output, shown here in bold text):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2:latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4:latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15:latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition    Row count    Commit count    Frag fixed memory    Frag varsize memory
0              26086             26086             1572864              557056
1              26329             26329             1605632              557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each **NDBCLUSTER** table, an **ALTER ONLINE TABLE ... REORGANIZE PARTITION** statement in the **mysql** client. After issuing the statement **ALTER ONLINE TABLE ips REORGANIZE PARTITION**, you can see using **ndb\_desc** that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80

1              13236          52515            1605632              557056
2              13105          13105            819200               294912
3              13093          13093            819200               294912

NDBT_ProgramExit: 0 - OK
```

### Note

Normally, **ALTER [ONLINE] TABLE table\_name REORGANIZE PARTITION** is used with a list of partition

identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new MySQL Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see [Section 12.1.7, “ALTER TABLE Syntax”](#).

In addition, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

### Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for a MySQL Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

### Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.** It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 192.168.0.4
Nodegroup = 65536

[mgm]
HostName = 192.168.0.10
Id = 10
```

```
[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

### Note

In MySQL Cluster NDB 7.2, it is no longer necessary to perform the initial start of the cluster using `--nowait-nodes` option with `ndbd` or `ndbmta` as it was in some earlier versions of MySQL Cluster.

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 192.168.0.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

### Note

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 192.168.0.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing MySQL Cluster tables cannot use the new nodes for data distribution until this has been done.)

## 16.5.13. Distributed MySQL Privileges for MySQL Cluster

MySQL Cluster NDB 7.2 introduces support for distributing MySQL users and privileges across all SQL nodes in a MySQL Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. In MySQL Cluster NDB 7.2 and later, an SQL file `ndb_dist_priv.sql` is provided with the MySQL Cluster distribution. This file can be found in the `share` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where `options` stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as MySQL `root`), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
-> FROM INFORMATION_SCHEMA.ROUTINES
-> WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
-> ORDER BY ROUTINE_TYPE;
```

ROUTINE_NAME	ROUTINE_SCHEMA	ROUTINE_TYPE
mysql_cluster_privileges_are_distributed	mysql	FUNCTION
mysql_cluster_backup_privileges	mysql	PROCEDURE
mysql_cluster_move_grant_tables	mysql	PROCEDURE
mysql_cluster_move_privileges	mysql	PROCEDURE
mysql_cluster_restore_local_privileges	mysql	PROCEDURE
mysql_cluster_restore_privileges	mysql	PROCEDURE
mysql_cluster_restore_privileges_from_local	mysql	PROCEDURE

```
7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to NDB. Two sets of copies are created in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine, and named by adding the suffix `_backup` to the original privilege table names.
- A set of distributed copies (using `NDBCLUSTER`). These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
mysql host user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `NO DATA - ZERO ROWS FETCHED, SELECTED, OR PROCESSED` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT(
-> 'Conversion ',
-> IF(mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
-> '.')
-> AS Result;
```

Result
Conversion succeeded.

```
1 row in set (0.00 sec)
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns `1` if all of the privilege tables are distributed; otherwise, it returns `0`.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
-> ORDER BY ENGINE;
```

TABLE_NAME	ENGINE
host_backup	MyISAM
db_backup	MyISAM
columns_priv_backup	MyISAM
user_backup	MyISAM
tables_priv_backup	MyISAM

```

proxies_priv_backup      MyISAM
procs_priv_backup        MyISAM
ndb_user_backup          ndbcluster
ndb_tables_priv_backup   ndbcluster
ndb_proxies_priv_backup  ndbcluster
ndb_procs_priv_backup    ndbcluster
ndb_host_backup          ndbcluster
ndb_db_backup            ndbcluster
ndb_columns_priv_backup  ndbcluster
+-----+-----+
14 rows in set (0.00 sec)

```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

### Note

Formerly, after `mysql_cluster_move_privileges` was executed, you sometimes needed to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges. In MySQL Cluster NDB 7.2.4 and later, this is no longer necessary, as SQL nodes automatically execute a `FLUSH PRIVILEGES` statement when joining a MySQL Cluster where distributed privileges are in use.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes privileges associated with views and stored routines. While automatic distribution of views and stored routines is not currently supported, you can attempt to distribute stored routines by issuing a statement such as `ALTER TABLE mysql.proc ENGINE = NDB`, but you must verify manually that any tables referenced by the stored routines exist on all SQL nodes, since MySQL Cluster has no support at the present time for doing this automatically. There is currently no way to distribute views among MySQL Cluster SQL nodes, other than by creating them manually on each SQL node. If you do this, you must make certain that all base tables referenced by the views use the `NDB` storage engine; otherwise, the views are likely to diverge very quickly.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS user db tables_priv columns_priv procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. In this case, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

### Important

Applications that access MySQL Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other `NDB` tables. In particular, you should keep in mind that *NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions.*

## 16.5.14. NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on `NDB` tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```

mysql> SHOW STATUS LIKE 'ndb_api%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 0 |
+-----+-----+

```

```

Ndb_api_wait_scan_result_count_session 0
Ndb_api_wait_meta_request_count_session 0
Ndb_api_wait_nanos_count_session 0
Ndb_api_bytes_sent_count_session 0
Ndb_api_bytes_received_count_session 0
Ndb_api_trans_start_count_session 0
Ndb_api_trans_commit_count_session 0
Ndb_api_trans_abort_count_session 0
Ndb_api_trans_close_count_session 0
Ndb_api_pk_op_count_session 0
Ndb_api_uk_op_count_session 0
Ndb_api_table_scan_count_session 0
Ndb_api_range_scan_count_session 0

+-----+-----+  
60 rows in set (0.00 sec)

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client.* This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as “`_session` variables”, with a leading underscore.

- *Slave counters (global)*

This set of counters relates to the `Ndb` objects used by the replication slave SQL thread, if any. If this `mysqld` does not act as a replication slave, or does not use `NDB` tables, then all of these counts are 0.

We refer to the related status variables as “`_slave` variables” (with a leading underscore).

- *Injector counters (global)*

Injector counters relate to the `Ndb` object used to listen to cluster events by the binlog injector thread. Even when not writing a binary log, `mysqld` processes attached to a MySQL Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as “`_injector` variables” (with a leading underscore).

- *Server (Global) counters (global)*

This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the `NDB` utility thread.

We refer to the status variables that correspond to these counters as “global variables” or “`mysqld`-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
```

Variable_name	Value
Ndb_api_wait_exec_complete_count_session	2
Ndb_api_wait_scan_result_count_session	0
Ndb_api_wait_meta_request_count_session	1

```

Ndb_api_wait_nanos_count_session      8144375
Ndb_api_bytes_sent_count_session       68
Ndb_api_bytes_received_count_session   84
Ndb_api_trans_start_count_session      1
Ndb_api_trans_commit_count_session     1
Ndb_api_trans_abort_count_session      0
Ndb_api_trans_close_count_session      1
Ndb_api_pk_op_count_session            1
Ndb_api_uk_op_count_session            0
Ndb_api_table_scan_count_session       0
Ndb_api_range_scan_count_session       0
Ndb_api_pruned_scan_count_session      0
Ndb_api_scan_batch_count_session       0
Ndb_api_read_row_count_session         1
Ndb_api_trans_local_read_row_count_session 1
+-----+-----+
18 rows in set (0.50 sec)

```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
-> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT | 4 |
| NDB_API_WAIT_SCAN_RESULT_COUNT | 3 |
| NDB_API_WAIT_META_REQUEST_COUNT | 28 |
| NDB_API_WAIT_NANOS_COUNT | 53756398 |
| NDB_API_BYTES_SENT_COUNT | 1060 |
| NDB_API_BYTES_RECEIVED_COUNT | 9724 |
| NDB_API_TRANS_START_COUNT | 3 |
| NDB_API_TRANS_COMMIT_COUNT | 2 |
| NDB_API_TRANS_ABORT_COUNT | 0 |
| NDB_API_TRANS_CLOSE_COUNT | 3 |
| NDB_API_PK_OP_COUNT | 2 |
| NDB_API_UK_OP_COUNT | 0 |
| NDB_API_TABLE_SCAN_COUNT | 1 |
| NDB_API_RANGE_SCAN_COUNT | 0 |
| NDB_API_PRUNED_SCAN_COUNT | 0 |
| NDB_API_SCAN_BATCH_COUNT | 0 |
| NDB_API_READ_ROW_COUNT | 2 |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2 |
| NDB_API_EVENT_DATA_COUNT | 0 |
| NDB_API_EVENT_NONDATA_COUNT | 0 |
| NDB_API_EVENT_BYTES_COUNT | 0 |
+-----+-----+
21 rows in set (0.09 sec)

```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```

mysql> SHOW STATUS LIKE 'ndb_api%event%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nondata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |
| Ndb_api_event_data_count | 0 |
| Ndb_api_event_nondata_count | 0 |
| Ndb_api_event_bytes_count | 0 |
+-----+-----+
6 rows in set (0.00 sec)

```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```

mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nondata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |
+-----+-----+
3 rows in set (0.00 sec)

```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

Counter Name	Description	Status Variables (by statistic type)			
		Session	Slave	Injector	Server
WaitExecComplete-Count	Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit implicit executes for blob operations and auto-increment not visible to clients.	Ndb_api_wait_exec_complete_count_session	Ndb_api_wait_exec_complete_count_slave	[none]	Ndb_api_wait_exec_complete_count
WaitScanResult-Count	Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.	Ndb_api_wait_scan_result_count_session	Ndb_api_wait_scan_result_count_slave	[none]	Ndb_api_wait_scan_result_count
WaitMetaRequest-Count	Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).	Ndb_api_wait_meta_request_count_session	Ndb_api_wait_meta_request_count_slave	[none]	Ndb_api_wait_meta_request_count
WaitNanosCount	Total time (in nanoseconds) spent waiting for some type of signal from the data nodes.	Ndb_api_wait_nanos_count_session	Ndb_api_wait_nanos_count_slave	[none]	Ndb_api_wait_nanos_count
BytesSentCount	Amount of data (in bytes) sent to the data nodes	Ndb_api_bytes_sent_count_session	Ndb_api_bytes_sent_count_slave	[none]	Ndb_api_bytes_sent_count
BytesRecvCount	Amount of data (in bytes) received from the data nodes	Ndb_api_bytes_received_count_session	Ndb_api_bytes_received_count_slave	[none]	Ndb_api_bytes_received_count
TransStartCount	Number of transactions started.	Ndb_api_transactions_start_count_session	Ndb_api_transactions_start_count_slave	[none]	Ndb_api_transactions_start_count
TransCommitCount	Number of transactions committed.	Ndb_api_transactions_commit_count_session	Ndb_api_transactions_commit_count_slave	[none]	Ndb_api_transactions_commit_count
TransAbortCount	Number of transactions aborted.	Ndb_api_transactions_abort_count_session	Ndb_api_transactions_abort_count_slave	[none]	Ndb_api_transactions_abort_count
TransCloseCount	Number of transactions aborted. (This value may be greater than the sum of <a href="#">TransCommitCount</a> and <a href="#">TransAbort-Count</a> .)	Ndb_api_transactions_close_count_session	Ndb_api_transactions_close_count_slave	[none]	Ndb_api_transactions_close_count
PkOpCount	Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to	Ndb_api_pk_ops_count_session	Ndb_api_pk_ops_count_slave	[none]	Ndb_api_pk_ops_count

Counter Name	Description	Status Variables (by statistic type)			
		Session	Slave	Injector	Server
	MySQL clients.				
<a href="#">UkOpCount</a>	Number of operations based on or using unique keys.	<a href="#">Ndb_api_uk_op_count_session</a>	<a href="#">Ndb_api_uk_op_count_slave</a>	[none]	<a href="#">Ndb_api_uk_op_count</a>
<a href="#">TableScanCount</a>	Number of table scans that have been started. This includes scans of internal tables.	<a href="#">Ndb_api_table_scan_count_session</a>	<a href="#">Ndb_api_table_scan_count_slave</a>	[none]	<a href="#">Ndb_api_table_scan_count</a>
<a href="#">RangeScanCount</a>	Number of range scans that have been started.	<a href="#">Ndb_api_range_scan_count_session</a>	<a href="#">Ndb_api_range_scan_count_slave</a>	[none]	<a href="#">Ndb_api_range_scan_count</a>
<a href="#">PrunedScanCount</a>	Number of scans that have been pruned to a single partition.	<a href="#">Ndb_api_pruned_scan_count_session</a>	<a href="#">Ndb_api_pruned_scan_count_slave</a>	[none]	<a href="#">Ndb_api_pruned_scan_count</a>
<a href="#">ScanBatchCount</a>	Number of batches of rows received. (A <i>batch</i> in this context is a set of scan results from a single fragment.)	<a href="#">Ndb_api_scan_batch_count_session</a>	<a href="#">Ndb_api_scan_batch_count_slave</a>	[none]	<a href="#">Ndb_api_scan_batch_count</a>
<a href="#">ReadRowCount</a>	Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations.	<a href="#">Ndb_api_read_row_count_session</a>	<a href="#">Ndb_api_read_row_count_slave</a>	[none]	<a href="#">Ndb_api_read_row_count</a>
<a href="#">TransLocalRead-RowCount</a>	Number of rows read from the data same node on which the transaction was being run.	<a href="#">Ndb_api_trans_local_read_row_count_session</a>	<a href="#">Ndb_api_trans_local_read_row_count_slave</a>	[none]	<a href="#">Ndb_api_trans_local_read_row_count</a>
<a href="#">DataEventsRecvd-Count</a>	Number of row change events received.	[none]	[none]	<a href="#">Ndb_api_event_data_count_injector</a>	<a href="#">Ndb_api_event_data_count</a>
<a href="#">NondataEvents-RecvdCount</a>	Number of events received, other than row change events.	[none]	[none]	<a href="#">Ndb_api_event_nondata_count_injector</a>	<a href="#">Ndb_api_event_nondata_count</a>
<a href="#">EventBytesRecvd-Count</a>	Number of bytes of events received.	[none]	[none]	<a href="#">Ndb_api_event_bytes_count_injector</a>	<a href="#">Ndb_api_event_bytes_count</a>

To see all counts of committed transactions—that is, all [TransCommitCount](#) counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_commit_count_slave | 0 |
| Ndb_api_trans_commit_count | 2 |
+-----+-----+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysql` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an NDB table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

Variable_name	Value
Ndb_api_wait_exec_complete_count_session	2
Ndb_api_wait_scan_result_count_session	0
Ndb_api_wait_meta_request_count_session	3
Ndb_api_wait_nanos_count_session	820705
Ndb_api_bytes_sent_count_session	132
Ndb_api_bytes_received_count_session	372
Ndb_api_trans_start_count_session	1
Ndb_api_trans_commit_count_session	1
Ndb_api_trans_abort_count_session	0
Ndb_api_trans_close_count_session	1
Ndb_api_pk_op_count_session	1
Ndb_api_uk_op_count_session	0
Ndb_api_table_scan_count_session	0
Ndb_api_range_scan_count_session	0
Ndb_api_pruned_scan_count_session	0
Ndb_api_scan_batch_count_session	0
Ndb_api_read_row_count_session	1
Ndb_api_trans_local_read_row_count_session	1

```
18 rows in set (0.00 sec)
```

```
mysql> USE test;
```

Database changed

```
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
```

Query OK, 0 rows affected (0.85 sec)

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

Variable_name	Value
Ndb_api_wait_scan_result_count_session	0
Ndb_api_wait_meta_request_count_session	17
Ndb_api_wait_nanos_count_session	706871709
Ndb_api_bytes_sent_count_session	2376
Ndb_api_bytes_received_count_session	3844
Ndb_api_trans_start_count_session	4
Ndb_api_trans_commit_count_session	4
Ndb_api_trans_abort_count_session	0
Ndb_api_trans_close_count_session	4
Ndb_api_pk_op_count_session	6
Ndb_api_uk_op_count_session	0
Ndb_api_table_scan_count_session	0
Ndb_api_range_scan_count_session	0
Ndb_api_pruned_scan_count_session	0
Ndb_api_scan_batch_count_session	0
Ndb_api_read_row_count_session	2
Ndb_api_trans_local_read_row_count_session	1

```
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
```

Query OK, 1 row affected (0.00 sec)

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

Variable_name	Value
Ndb_api_wait_exec_complete_count_session	11
Ndb_api_wait_scan_result_count_session	6
Ndb_api_wait_meta_request_count_session	20
Ndb_api_wait_nanos_count_session	707370418
Ndb_api_bytes_sent_count_session	2724
Ndb_api_bytes_received_count_session	4116
Ndb_api_trans_start_count_session	7
Ndb_api_trans_commit_count_session	6
Ndb_api_trans_abort_count_session	0
Ndb_api_trans_close_count_session	7
Ndb_api_pk_op_count_session	8
Ndb_api_uk_op_count_session	0
Ndb_api_table_scan_count_session	1
Ndb_api_range_scan_count_session	0
Ndb_api_pruned_scan_count_session	0
Ndb_api_scan_batch_count_session	0
Ndb_api_read_row_count_session	3
Ndb_api_trans_local_read_row_count_session	2

```
+-----+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.
- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer ( $706871709 - 820705 = 706051004$  nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` ( $707370418 - 706871709 = 498709$  ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

On platforms with without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

## 16.5.15. ndbmemcache

### 16.5.15.1. Overview

*Memcached* is a distributed in-memory caching server using a simple text-based protocol, commonly used for key-value data stores, with clients available for many platforms and programming languages. The most recent release of the `memcached` server is available from [memcached.org](http://memcached.org).

The Memcache API for MySQL Cluster is available beginning with MySQL Cluster NDB 7.2.2. This API is implemented as a loadable storage engine for memcached version 1.6 and later, which employs a storage engine architecture. This API can be used to provide a persistent MySQL Cluster data store which is accessible employing the memcache protocol. It is also possible for the `memcached` server to provide a strictly defined interface to existing MySQL Cluster tables such that an administrator can control exactly which tables and columns are referenced by particular memcache keys and values, and which operations are allowed on these keys and values.

The standard `memcached` caching engine is included in the MySQL Cluster distribution. Each memcache server, in addition to providing direct access to data stored in MySQL Cluster, is able to cache data locally and serve (some) requests from this local cache. As with table and column mappings, cache policies are configurable based on a prefix of a memcache key.

### 16.5.15.2. Compiling MySQL Cluster with Memcache Support

Support for the Memcache API is built automatically using the `memcached` and `libevent` sources included in the MySQL Cluster sources when compiling MySQL Cluster NDB 7.2.3 or later from source. By default, `make install` places the `memcached` binary in the MySQL Cluster installation `bin` directory, and the `ndbmemcache` engine shared object file `ndb_engine.so` in the installation `lib` directory.

You can disable use of the bundled `memcached` when building `ndbmemcache`, by using `-DWITH_BUNDLED_MEMCACHED=OFF`; you can instead use your own system's `memcached` server and sources, installed in `path`, with `-DWITH_BUNDLED_MEMCACHED=OFF -DMEMCACHED_HOME=path`. You can also cause your system's version of `libevent` to be used, rather than the version bundled with MySQL Cluster, by using the `-DWITH_BUNDLED_LIBEVENT=OFF` option.

For additional information about CMake options relating to `ndbmemcache` support, see [CMake Options for Compiling MySQL Cluster](#).

For general information about building MySQL Cluster, see [Section 16.2.1.3, “Building MySQL Cluster from Source on Linux”](#), and [Section 16.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”](#). For information about building MySQL Server from source, see [Section 2.9, “Installing MySQL from Source”](#), as well as [Section 2.9.4, “MySQL Source-Configuration Options”](#).

### 16.5.15.3. memcached command line options

The following list contains `memcached` command line options that are of particular interest or usefulness when working with `ndbmemcache`.

- `-E so_file`

Specifies an engine (module) to be dynamically loaded on startup by memcached (version 1.6 or later).

If this option is not specified, memcached tries to load the default engine, which provides the same caching engine as used in memcached 1.4 and previous versions

To load the NDB engine, use this option as shown here:

```
-E /path/to/ndb_engine.so
```

- `-e "configuration_string"`

Specifies options for use by the loaded engine. Options are given as *option=value* pairs separated by semicolons. The complete string should be quoted to prevent the possibility that the shell might interpret the semicolon as a command separator. All options to be passed to the NDB memcached engine must be specified in this fashion, as shown in the following example:

```
shell> memcached -E lib/ndb_engine.so -e "connectstring=maddy:1186;role=dev"
```

See [Section 16.5.15.4, “NDB Engine Configuration”](#) for a list of NDB memcached engine configuration options.

- `-t number_of_worker_threads`

Sets the number of worker threads to be used by memcached. Because memcached uses an event-driven model in which each worker thread should be able to saturate a CPU core, the number of worker threads should be approximately the same as the number of CPU cores that memcached is to use.

In some cases, adding worker threads does not improve performance unless you also provide additional connections to MySQL Cluster. The default (4 memcached threads and 2 cluster connections) should work in most cases.

- `-p tcp_port`

The default TCP port is port 11211.

- `-U udb_port`

The default UDP port is port 11211. Setting this option to 0 disables UDP support.

- `-h`

Causes `memcached` to print help information.

For general information `memcached` command line options, see the documentation at <http://code.google.com/p/memcached/wiki/NewStart>.

## 16.5.15.4. NDB Engine Configuration

**NDB memcache engine configuration options.** The NDB engine supports the following configuration options for use with `memcache -e` (see [Section 16.5.15.3, “memcached command line options”](#)):

- `debug={true|false}`

Enables writing of debug tracing output to `stderr` or the memcached log file, as shown in this example:

```
shell> memcached -E lib/ndb_engine.so -e "debug=true"
```

Because the debug output can be quite large, you should enable this option as a diagnostic tool only, and not in production.

By default, this option is `false`.

- `connectstring=connect_string`

This option takes as its value a MySQL Cluster connectstring (see [Section 16.3.2.3, “The MySQL Cluster Connectstring”](#)) pointing

to the primary MySQL Cluster—that is, the MySQL Cluster in which the `ndbmemcache` configuration database is stored, as shown here:

```
shell > memcached -E lib/ndb_engine.so -e "connectstring=sam:1186;debug=true"
```

The default value is `localhost:1186`.

- `reconf={true|false}`

Enables online reconfiguration (reloading of the configuration stored in the `ndbmemcache` information database).

This option is enabled (`true`) by default.

- `role=role_name`

Sets the role assumed by this memcached server. A role corresponds to a set of key-prefix mappings described in the `ndbmemcache` configuration database, identified by a `role_name` found in the `ndbmemcache.memcache_server_roles` table.

The default role is `default_role`.

An example is shown here:

```
shell> memcached -E lib/ndb_engine.so -e "role=db-only"
```

- `scheduler=scheduler_name:scheduler_options`

This option controls some advanced aspects of how the NDB engine sends requests to MySQL Cluster. The `scheduler_name` of the default scheduler or *S-scheduler* is `S`. An S-scheduler option takes the form of a single letter followed by a number; multiple S-scheduler options are separated by commas. In most cases, the default value `S:c0,f0,t1` is sufficient.

These S-scheduler options are described in the following list:

- `c`: Number of connections to NDB. Possible values are in the range 0-4 inclusive, with 0 (the default) causing this number to be calculated automatically. Using 1, 2, 3, or 4 causes that number of connections to be created.
- `f`: Can be either 0 or 1; setting to 1 enables force-send. The default is 0 (force-send disabled).
- `t`: Sets the send-thread timer to 1-10 milliseconds (inclusive). The default is 1.

**Initial Configuration.** When a the NDB engine starts up, its most important command-line arguments are the cluster connectstring and server role. The connectstring is used to connect to a particular cluster, called the primary cluster, which contains a configuration schema. The tables in the configuration schema are read to retrieve a set of key-prefix mappings for the given server role (see the `ndbmemcache` configuration schema). Those mappings instruct the server how to respond to memcache operations on particular keys, based on the leftmost part of the key. For instance, they may specify that data is stored in particular columns of a certain table. This table may be stored in the same cluster as the configuration schema, or in a different cluster. A memcache server may have connections to several different clusters, and many memcache servers may connect to a single cluster but with a variety of roles.

**The `ndbmemcache` configuration schema.** When the memcache NDB engine starts up, it connects to a cluster, and looks for the `ndbmemcache` configuration schema there. If the schema is not found, it shuts down.

The schema is described (with full comments) in the file `ndb_memcache_metadata.sql`

The main concept of the schema is a key-prefix mapping. This takes a prefix of a memcache key and maps it to a specific container table, on a particular cluster, with a particular cache policy.

A server role is defined as a set of key-prefix mappings that a memcached server will implement.

Whenever a memcached server is started with a particular server role (from the command-line arguments), that server role must exist in the `ndbmemcache.server_roles` table.

The configuration tables

Table Name	Description
<code>meta</code>	The meta table describes the version number of the <code>ndbmemcache</code> tables. It should be considered as a read-

Table Name	Description
	only table.
<code>ndb_clusters</code>	For each cluster, this table holds a numeric cluster-id and a connectstring. The <code>microsec_rtt</code> column is used for performance tuning. It is recommended to use the default value of this column. See <a href="#">Autotuning</a> .
<code>cache_policies</code>	This table maps a policy name to a set of get, set, delete, and flush policies. The <code>policy_name</code> column is used as the key (there is no numeric policy id).  Additional information about cache policies can found in the text following the table.
<code>containers</code>	The containers table describes how the memcached server can use a database table to store data.  Additional information about containers can found in the text following the table.
<code>mem-cache_server_roles</code>	The <code>memcache_server_roles</code> table maps a role name to a numeric ID and a <code>max_tps</code> specifier, which is used for performance tuning. See <a href="#">Autotuning</a> . It is recommended to use the default value.  This table also has an <code>update_timestamp</code> column. This column can be updated to enable online reconfiguration. See <a href="#">Online reconfiguration</a> .  Additional information about server roles can found in the text following the table.
<code>key_prefixes</code>	In this table, the leftmost part of a memcache key is paired with a cluster ID, container, and cache policy to make a <i>key prefix mapping</i> .  Additional information about key prefix mappings can found in the text following the table.

**Cache policies.** There are four policy types: `get_policy`, `set_policy`, `delete_policy`, and `flush_from_db`. These are described in the following paragraphs.

`get_policy` determines how the memcached server interprets `GET` commands. Possible values and their meanings are shown in the following list:

- `cache_only`: The server searches in its local cache only.
- `ndb_only`: The server searches in the MySQL Cluster database only.
- `caching`: The server searches the local cache first, then the MySQL Cluster database.
- `disabled`: `GET` commands are not permitted.

The `set_policy` determines how the memcached server interprets `SET`, `INSERT`, and `REPLACE` commands. Possible `set_policy` values and their meanings are listed here:

- `cache_only`: The server updates the value in its local cache only.
- `ndb_only`: The server updates the value stored in MySQL Cluster only.
- `caching`: The server updates the value stored in MySQL Cluster, and then stores a copy of that value in its local cache.
- `disabled`: `SET`, `INSERT`, and `REPLACE` commands are not allowed.

`delete_policy` describes how the memcached server interprets `DELETE` commands. It can take on the values shown and described in the following list:

- `cache_only`: The server deletes the value from its local cache only.

- `ndb_only`: The server deletes the value from the MySQL Cluster database only.
- `caching`: The server deletes the value from both the database and its local cache.
- `disabled`: `DELETE` operations are not allowed.

`flush_from_db` determines how the memcached server interprets a `FLUSH_ALL` command with regard to data stored in the MySQL Cluster database, as shown here:

- `true`: `FLUSH_ALL` commands cause data to be deleted from the MySQL Cluster database.
- `false`: `FLUSH_ALL` commands do not affect the MySQL Cluster database.

**containers table columns.** The columns in the `containers` table are described in the following list:

- `name`: Name of container; primary key of table.
- `db_schema`: Name of database (schema) holding container table.
- `db_table`: table name of container table.
- `key_columns`: List of columns that map to the memcache key. Most keys are one-part keys, but a key can have up to four parts, in which case multiple columns are listed and separated by commas.
- `value_columns`: List of columns that map to the memcache value. It can also contain a comma-separated list of up to 16 value columns.
- `flags`: Currently unimplemented; it is intended hold either a numeric value which is used as the memcache `FLAGS` value for the entire container, or the name of that column of the container table used to store this value.
- `increment_column`: Name of the column in the container table which stores the numeric value used in memcached `INCR` and `DECR` operations. If set, this must be a `BIGINT UNSIGNED` column.
- `cas_column`: Name of the column in the container table storing the memcache CAS value. If set, it must be a `BIGINT UNSIGNED` column.
- `expire_time_column`: Currently unimplemented.

### Key mappings.

- `server_role_id` is a numeric server role identifier which references the `memcache_server_roles` table
- `key_prefix` is a string that corresponds to the leftmost part of the memcache key. If this string is empty, then the defined prefix will be the "default prefix". The default prefix matches any memcache key that does not match some more specific prefix.
- `cluster_id` is an int that references the `ndb_clusters` table
- `policy` is a string that references a policy name in the `cache_policies` table
- `container` is a container name that references the `containers` table

### Non-configuration tables

Table Name	Description
<code>last_memcached_session</code>	<p>This table is not part of the configuration schema, but is an informative logging table. It records the most recent login time of each memcached server using the configuration.</p> <ul style="list-style-type: none"> <li>• <code>ndb_node_id</code> is an int recording the API node id of the server</li> </ul>

Table Name	Description
	<ul style="list-style-type: none"> <li>hostname is the hostname of the memcached server</li> <li>server_role is the server role of the server at signon time</li> <li>signon_time is a timestamp recording the memcached startup time</li> </ul> <p>In the case of online reconfiguration, signon_time records the time of the latest reconfiguration, not the time of startup. This is an unintended consequence and might be considered a bug.</p>
demo_table	demo_table is the container table used with default key prefix in the default server role. It is used to demonstrate SET and GET operations as well as INCR, DECR, and CAS, with one key column and one value column.
demo_table_tabs	demo_table_tabs is the container table for the "demo_tabs" container, which is used with the key prefix "t:" in the default server role. It is used to demonstrate one key column with multiple value columns. In memcache operations, the value columns are represented as a tab-separated list of values.

#### Predefined configuration objects

**Predefined clusters.** A single `ndb_cluster` record is predefined, referring to the primary cluster (the one where configuration data is stored) as cluster id 0. Id 0 should always be reserved for the primary cluster.

#### Predefined cache policies

- "memcache-only" : a policy in which all memcache operations are to use local cache only
- "ndb-only" : a policy in which all memcache operations use the MySQL Cluster database, except for `FLUSH_ALL`, which is disabled
- "caching" : a policy with `get_policy`, `set_policy`, and `delete_policy` all set to "caching". `FLUSH_ALL` is disabled.
- "caching-with-local-deletes": a policy in which `get_policy` and `set_policy` are set to caching, but `delete_policy` is set to "cache-only", and `FLUSH_ALL` is disabled.
- "ndb-read-only": a policy in which `get_policy` is set to `ndb_only`, so that memcache GET operations use the database, but all other memcache operations are disabled
- "ndb-test": a policy like "ndb-only" with the difference that `FLUSH_ALL` is allowed (`flush_from_db`) is true. This is the only predefined policy with `flush_from_db` enabled. This policy is enabled by default for the default server role, so that the entire memcache command set can be demonstrated.

#### Predefined containers

- "demo\_table": a container using the table `ndbmemcache.demo_table` as a container table
- "demo\_tabs": a container using the table `ndbmemcache.demo_table_tabs` as a container table

#### Predefined memcache server roles and their key prefixes

- "default\_role" (role id 0)
  - "": The empty (default) prefix uses the `ndb-test` policy and the `demo_table` container
  - "mc:" Memcache keys beginning with "mc:" are treated according to the memcache-only cache policy
  - "t:" Memcache keys beginning with "t:" use the `ndb-test` cache policy and the `demo_tabs` container
- The "db-only" role (role id 1)

"": the empty (default) prefix uses the ndb-only role and demo\_table container

The "t:" prefix uses the ndb-only role and demo\_tabs container

- The "mc-only" role (role id 2)

"": The empty (default) prefix uses local caching only for all keys

- The "ndb-caching" role (role id 3)

"": The empty (default) prefix uses the "caching" cache policy and "demo\_table" container for all keys

**Configuration versioning and upgrade.** The configuration schema is versioned, and the version number is stored in the ndbmem-cache.meta table. The NDB Engine begins the configuration process by reading the schema version number from this table. As a rule, newer versions of the NDB engine will remain compatible with older versions of the configuration schema.

STABILITY NOTE: consider this section "unstable" & subject to change

**Performance Tuning.** Two parameters are used to tune performance of the NDB memcache engine. The parameters are stored in the configuration schema: the "usec\_rtt" value of a particular cluster, and the "max\_tps" value of a memcache server role. These values are currently used in two ways: to configure the number of connections to each cluster, and to configure a particular fixed number of concurrent operations supported from each connection.

**Autotuning.** Autotuning uses an estimated round trip time between cluster data nodes and a target rate of throughput to determine the ideal number of cluster connections and transactions per connection for a given workload. Autotuning parameters are described in the next few paragraphs.

- `usec_rtt`: The round trip time, in microseconds, between cluster nodes. The default value is 250, which is typical for a MySQL Cluster on a local switched ethernet. To represent a cluster with higher inter-node latency (wider area), a higher value should be used.
- `max_tps`: The desired throughput from a server. This value is a heuristic, and does not in any way express either a floor or a ceiling on the actual throughput obtained. The default value (100000) is reasonable in most cases.

These values are used, as described in the next few paragraphs, to calculate an optimum number of cluster connections with a given transactions-per-second capacity..

**Number of cluster connections.** The NDB Engine scheduler attempts to open 1 cluster connection per 50000 transactions per second (TPS). This behavior can be overridden by using a scheduler configuration string (see [Section 16.5.15.4, "NDB Engine Configuration"](#).) If the scheduler fails to open a second or subsequent connection to a cluster—for example, because a node id is not available—this is not a fatal error; it will run with only the connections actually opened.

**Number of transactions per connection.** We assume that a transaction takes 5 times the cluster round trip time to complete. We can obtain the total number of in-flight transactions by dividing the server's `max_tps` by  $5 * rtt$  (in seconds). These in-flight transaction objects are evenly distributed among the cluster connections.

**Tuning example.** The following example starts with the default values `usec_rtt` = 250 and `max_tps` = 100000, and assumes a memcached server with 4 worker threads.

- 100000 TPS divided by 50000 is 2, and the server opens two NDB cluster connections.
- Transaction time in microseconds = 250  $\mu$ s round trip time \* 5 round trips = 1250  $\mu$ s.
- Transactions per connection per second =  $1000000 / tx\_time\_in\_usec = 1000000 / 1250 = 800$ .
- Total Ndb objects =  $max\_tps / tx\_per\_ndb\_per\_sec = 100000 / 800 = 125$ .
- $125 \text{ Ndb objects} / 2 \text{ connections} = 63 \text{ Ndb objects per connection (rounding upward)}$ .
- (Rounding upward once more) each of 4 worker threads gets 32 Ndb objects

**Online reconfiguration.** It is possible to reconfigure the key-prefix mappings of a running NDB engine without restarting it. This is done by committing a change to the configuration schema, and then updating the `update_timestamp` column of a particular server role in the memcache server roles table. The updating of the timestamp causes an event trigger to fire, so that the memcache server receives notification of the event.

Online reconfiguration can be disabled by using the `-e reconf=false` option on the command line.

Online reconfiguration can be used to connect to new clusters and to create new key-prefix mappings. However, it cannot be used to reset autotuning values on existing connections.

Online reconfiguration is a risky operation that could result in memcache server crashes or data corruption, and is used extensively in the mysql test suite. However, it is not recommended for reconfiguring a production server under load.

The `stats reconf` command can be run before and after online reconfiguration to verify that the version number of the running configuration has increased. Verification of reconfiguration is also written into the memcached log file.

### 16.5.15.5. Memcache protocol commands

The NDB engine supports the complete set of memcache protocol commands. When a newly installed server is started with the default server role and configuration schema, you should be able to run `memcapable`, a memcache-server verification tool, and see all tests pass. After a configuration has been customized, however—for instance, by disabling the `FLUSH_ALL` command—some `memcapable` tests are expected to fail.

**GET, SET, ADD, REPLACE, and DELETE operations.** Each of these operations is always performed according to a cache policy associated with the memcache key prefix. It may operate on a locally cached item, an item stored in the database, or both. If an operation has been disabled for the prefix, the developer should be sure to test the disabled operation, since it may fail silently, or with a misleading response code.

**CAS.** CAS, in the memcache protocol, refers to a “compare and set” value, which is used as a sort of version number on a cached value, and enables some optimistic application behavior

If a container includes a CAS column, the ndb engine will generate a unique CAS ID every time it writes a data value, and store it in the CAS column.

Some memcache operations include CAS checks, such as the ASCII CAS update which has the semantics “update this value, but only if its CAS id matches the CAS id in the request”. These operations are supported by the NDB engine. The check of the stored CAS ID against the application's CAS ID is performed in an atomic operation on the NDB data node. This allows CAS checks to work correctly even when multiple memcached servers access the same key-value pair.

If CAS ID checks are in use, and additional MySQL Cluster APIs other than memcached are being used to manipulate the data, then the applications using those APIs are responsible for invalidating the stored CAS IDs whenever they update data. They can do this by setting the stored CAS ID value to 0 or `NULL`.

The CAS ID is generated using a scheme that attempts to prevent different servers from generating overlapping IDs. This scheme can be considered a best effort, but not a guarantee, of uniqueness. The scheme constructs an initial CAS as follows:

Part of the 32-bit Cluster GCI from the primary cluster at memcached startup time is used for the high-order bits of the 64-bit CAS ID

Part of the unique cluster node id in the primary cluster used when fetching configuration is used for middle-order bits of the CAS ID

An incrementing counter in the low-order bits of the CAS ID is at least 28-bits wide.

While the NDB engine generates one sequence of CAS IDs, the default engine—used for caching values in local memcached servers—generates a different sequence. Not all combinations of CAS behavior and cache policies have been tested, so any application developer wishing to use CAS should thoroughly test whether a particular configuration behaves as desired.

**FLUSH\_ALL.** `FLUSH_ALL` is implemented as follows: First, the NDB engine iterates over all configured key-prefixes. For any prefix whose cache policy enables a database flush (`flush_from_db` is `true`), it performs a scanning delete of every row in that prefix's container table. Other prefixes are ignored. This can be a slow operation if the table is large, and some memcache clients may time out before the `DELETE` operation is complete. After all database deletes are complete, the `FLUSH_ALL` command is forwarded to the standard caching engine, which sets a flag invalidating all cached data.

**INCR and DECR.** All `INCR` and `DECR` operations are pushed down to the NDB data nodes and performed atomically there. This allows multiple memcached servers to increment or decrement the same key and be guaranteed a unique value each time.

The `INCR` and `DECR` operations have clearer and more useful semantics in the binary memcache protocol than in the ASCII protocol. The binary protocol is recommended.

The memcached ASCII protocol introduces some ambiguities in the handling of `INCR` and `DECR`, and forces the NDB engine to work in `dup_numbers` mode, in which the `value_column` and the `math_column` must mirror each other.

`dup_numbers` mode is enabled for key prefixes that meet all of the following conditions:

- The container includes a math column, AND
- The container includes a single value column, AND
- The data type of the value column is non-numeric

In `dup_numbers` mode, the following special behavior applies:

- Whenever an ASCII `SET`, `ADD`, or `REPLACE` command sets a value that could be interpreted as numeric, and the container defines a `math_column`, then the text value is stored in the value column and the numeric value is also stored in the math column.
- Whenever an ASCII `INCR` or `DECR` command is performed, the text value in that container's value column is set to `NULL`.
- Whenever a memcached `GET` command is issued, and the container's value column is `NULL`, but the container's math column is not `NULL`, then the math value is returned to the client.

**APPEND and PREPEND.** The memcache `APPEND` and `PREPEND` operations are implemented as a single transaction which involves a read of the existing value with an exclusive lock, followed by a write of the new value. The read and write are grouped atomically into a transaction, but unlike `INCR` and `DECR`, which can run natively on the data nodes, `APPEND` and `PREPEND` are executed inside the memcached server. This means that multiple memcached servers can contend to `APPEND` and `PREPEND` the same value, and that no updates will be lost, but this contention relies on locking behavior that could cause noticeably increased latency.

**STATS.** A memcached server can provide many sets of statistics; use `STATS KEYWORD` from a login shell.

All statistics usually available from the memcached 1.6 core and the default engine are available. For instance, `STATS`, `STATS SLABS`, and `STATS SETTINGS` are all currently supported as described in the memcached documentation. Some special sets of statistics are available from the NDB engine, using the `STATS` commands described in the following list:

- `STATS NDB`: Returns NDB API statistics for each NDB cluster connection. These are the same internal statistics which are available as system status variables from the MySQL Server. See [Section 16.5.14, “NDB API Statistics Counters and Variables”](#), for more information.
- `STATS SCHEDULER`: Returns statistics for the S scheduler. All of these statistics are reported on the cluster connection level.
  - `cl%d.conn%d.sent_operations`: Records the number of operations sent from the connection's send thread to the cluster data nodes.
  - `cl%d.conn%d.batches`: Records the number of operation batches sent from the send thread to the data nodes. Each batch contains one or more operations. `sent_operations / batches` can be used to compute the average batch size.
  - `cl%d.conn%d.timeout_races`: This records a rare race condition that may occur in the send thread. It is expected to be 0, or to be a very low number compared to `sent_operations`.
- `stats reconf`: If the NDB engine is currently loading a new configuration, command returns the single-line message `Loading revno`, where `revno` is the version number of the configuration being loaded.

Otherwise, this command returns the statistical message `Running revno`.

`revno` starts at 1 when the memcached server begins running, and is incremented by 1 for each online reconfiguration.

## 16.5.15.6. The memcached log file

Whenever the [NDB](#) memcache engine is initialized, it writes a message including a timestamp and version number to its log file, as shown here:

```
12-Oct-2011 13:40:00 PDT NDB Memcache 5.5.15-ndb-7.2.1 started
[NDB 7.2.1; MySQL 5.5.15]
```

It also logs its attempt to connect to a primary cluster:

```
Contacting primary management server (localhost:1186) ...
Connected to "localhost:1186" as node id 4.
```

Upon successfully fetching initial configuration data, the memcache engine logs a summary message describing the configuration similar to what is shown here:

```
Retrieved 3 key prefixes for server role "default_role"
The default behavior is that:
  GET uses NDB only
  SET uses NDB only
  DELETE uses NDB only
The 2 explicitly defined key prefixes are "mc:" ( ) and "t:" (demo_table_tabs)
Server started with 4 threads.
```

The memcache engine also logs the establishment of each additional cluster connection, as shown here:

```
Connected to "" as node id 5.
```

A [priming the pump...](#) message indicates that the engine is about to prefetch a pool of transaction objects (API Connect Records). It is followed by a [done ...](#) message indicating how much time was used by prefetching. The server is not ready to respond to clients until after the prefetching is completed.

```
Priming the pump ...
Scheduler: using 2 connections to cluster 0
Scheduler: starting for 1 cluster; c0,f0,t1
done [0.579 sec].
```

Once the NDB engine has finished initializing, memcached prints a message verifying that the engine was loaded, and enumerating some of its features:

```
Loaded engine: NDB Memcache 5.5.15-ndb-7.2.1
Supplying the following features: compare and swap, persistent storage, LRU
```

If online reconfiguration is enabled, the NDB engine logs each reconfiguration, along with a summary of the new configuration, similar to what is shown here:

```
Received update to server role default_role
Retrieved 3 key prefixes for server role "default_role".
The default behavior is that:
  GET uses NDB only
  SET uses NDB only
  DELETE uses NDB only.
The 2 explicitly defined key prefixes are "mc:" ( ) and "t:" (demo_table_tabs)
ONLINE RECONFIGURATION COMPLETE
```

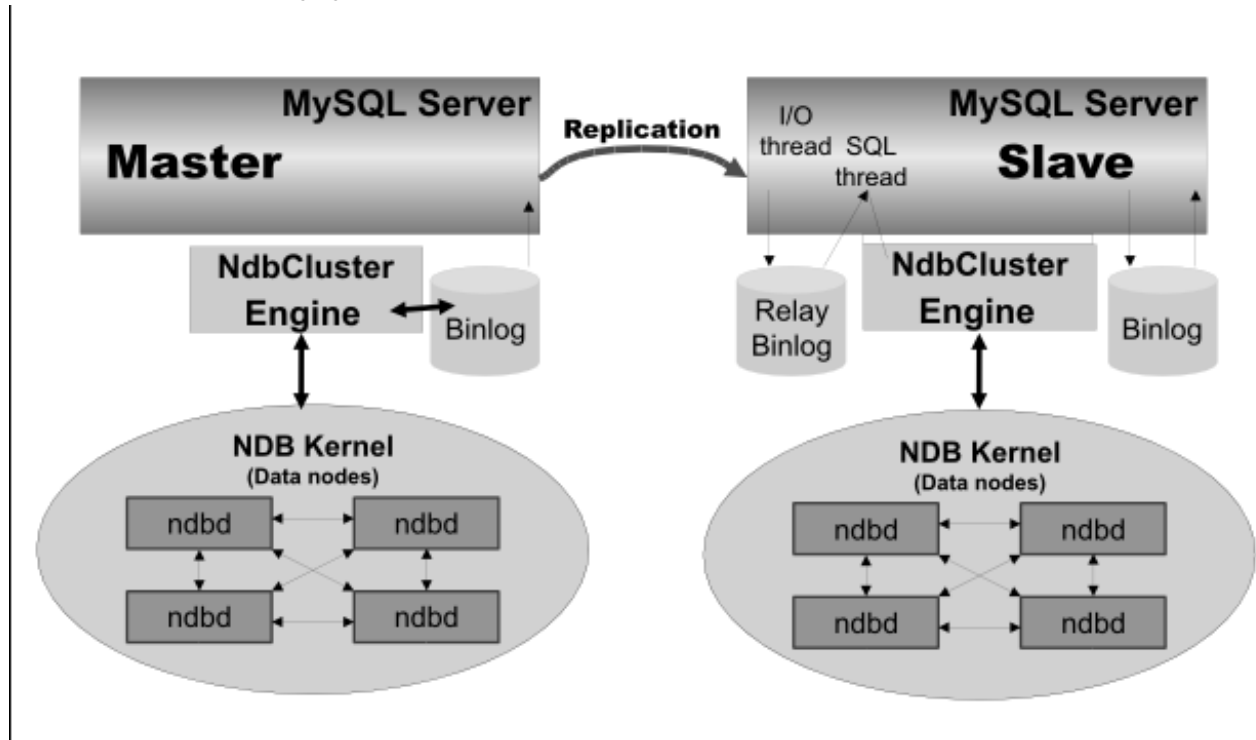

On shutdown, memcached logs the shutdown sequence's initialization and completion, and the NDB engine's scheduler logs its own shutdown as well:

```
Initiating shutdown
Shutting down scheduler.
Shutdown completed.
```

## 16.6. MySQL Cluster Replication

MySQL Cluster supports *asynchronous replication*, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 15, Replication](#)).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the [NDB](#) storage engine for clustering functionality, it is not necessary to use [NDB](#) as the storage engine for the slave’s copies of the replicated tables (see [Replication from NDB to non-NDB tables](#)). However, for maximum availability, it is possible (and preferable) to replicate from one MySQL Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log (*binlog*). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with MySQL Cluster and MySQL Cluster Replication, see [Section 16.6.9.2, “Point-In-Time Recovery Using MySQL Cluster Replication”](#).

**NDB API `_slave` status variables.** NDB API counters can provide enhanced monitoring capabilities on MySQL Cluster replication slaves. These are implemented as NDB statistics `_slave` status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a slave in MySQL Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated [NDB](#) tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting MySQL Cluster Replication. [Section 16.5.14, “NDB API Statistics Counters and Variables”](#), provides additional information.

**Replication from [NDB](#) to non-[NDB](#) tables.** It is possible to replicate [NDB](#) tables from a MySQL Cluster acting as the master to tables using other MySQL storage engines such as [InnoDB](#) or [MyISAM](#) on a slave `mysqld`. However, because of differences between the version of `mysqld` provided with MySQL Cluster and that included with MySQL Server 5.5, the slave server must also use a `mysqld` binary from the MySQL Cluster distribution. See [Section 16.6.2, “General Requirements for MySQL Cluster Replication”](#).

## 16.6.1. MySQL Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Symbol or Abbreviation	Description (Refers to...)
<i>M</i>	The cluster serving as the (primary) replication master
<i>S</i>	The cluster acting as the (primary) replication slave
<code>shellM&gt;</code>	Shell command to be issued on the master cluster
<code>mysqlM&gt;</code>	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
<code>mysqlM*&gt;</code>	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
<code>shellS&gt;</code>	Shell command to be issued on the slave cluster
<code>mysqlS&gt;</code>	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster
<code>mysqlS*&gt;</code>	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
<i>C</i>	Primary replication channel
<i>C'</i>	Secondary replication channel
<i>M'</i>	Secondary replication master
<i>S'</i>	Secondary replication slave

## 16.6.2. General Requirements for MySQL Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in [Section 16.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 15.1.2, “Replication Formats”](#).

### Important

If you attempt to use MySQL Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see [Section 16.6.4, “MySQL Cluster Replication Schema and Tables”](#)). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

In all MySQL Cluster NDB 6.x and 7.x releases, the default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where *id* is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see [Section 15.4.2, “Replication Compatibility Between MySQL Versions”](#)). It is due to such differences between the binaries in the MySQL Cluster and MySQL Server 5.5 distributions that MySQL Cluster Replication has the additional requirement that both `mysqld` binaries come from a MySQL Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same MySQL Cluster distribution for all master and slave `mysqld` binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

### Note

It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.

- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see [Section 15.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more specific information concerning the differences between the two replication formats.

### 16.6.3. Known Issues in MySQL Cluster Replication

This section discusses known problems or issues when using replication with MySQL Cluster NDB 7.2.

**Loss of master-slave connection.** A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the [MaxBufferedEpochs](#) and [TimeBetweenEpochs](#) configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master's binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. MySQL Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of [SHOW SLAVE STATUS](#), and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See [Section 16.6.8, “Implementing Failover with MySQL Cluster Replication”](#), for more information about what to do in such circumstances.

#### Important

Because MySQL Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master [mysqld](#) on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see [Section 16.6.7, “Using Two Replication Channels for MySQL Cluster Replication”](#), and [Section 16.6.8, “Implementing Failover with MySQL Cluster Replication”](#).

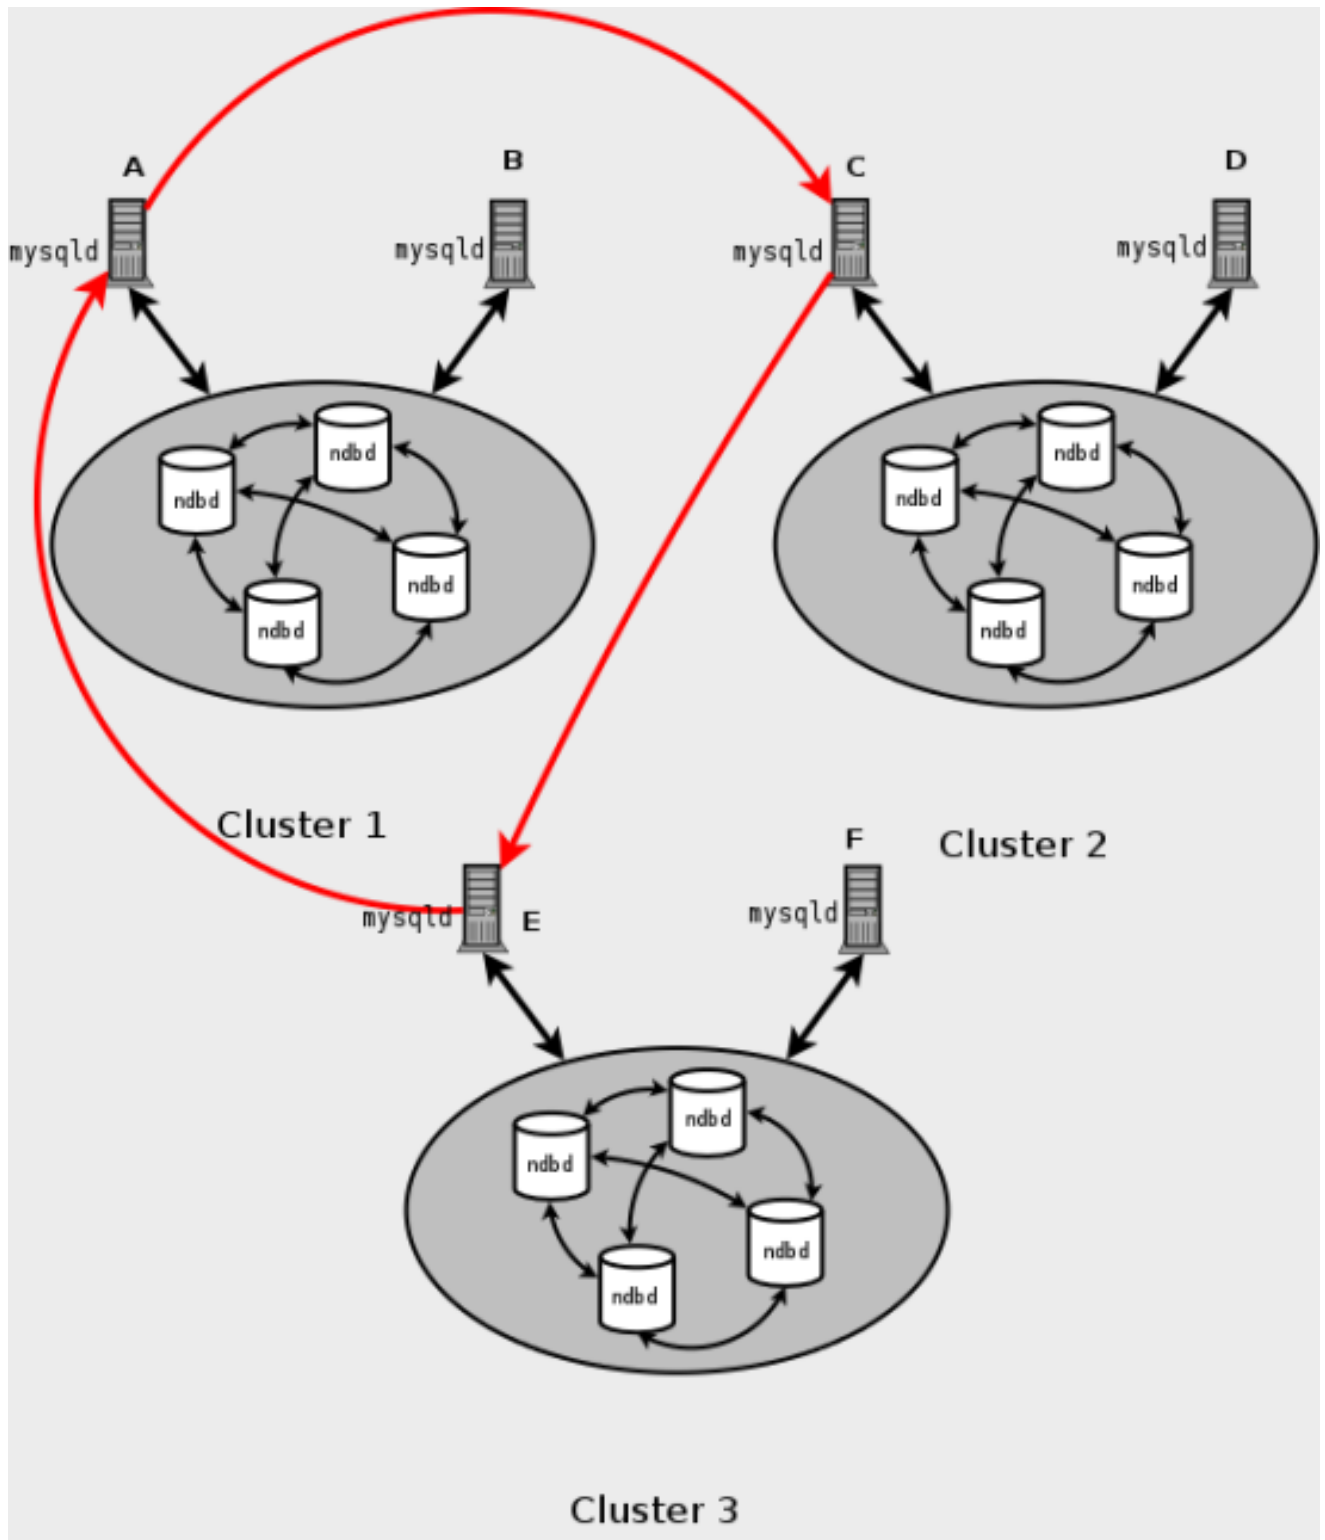

However, if you are replicating from a standalone MySQL server to a MySQL Cluster, one channel is usually sufficient.

**Circular replication.** MySQL Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1, thus completing the circle. Each MySQL Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the [--log-slave-updates](#) option

This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

#### Note

The **NDB** storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise

break circular replication of MySQL Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`. This is also required for multi-master replication when using MySQL Cluster. (Bug #31609)

It is not necessary to set `slave_exec_mode` in MySQL Cluster replication; MySQL Cluster does this automatically for all `NDB` tables and ignores any attempts to set this variable explicitly.

**MySQL Cluster replication and primary keys.** In the event of a node failure, errors in replication of `NDB` tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all `NDB` tables being replicated have primary keys.

**MySQL Cluster Replication and Unique Keys.** In older versions of MySQL Cluster, operations that updated values of unique key columns of `NDB` tables could result in duplicate-key errors when replicated. This issue is solved for replication between `NDB` tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by `NDB`. Thus, updates of unique keys when replicating from `NDB` to a different storage engine such as `MyISAM` or `InnoDB` are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using `NDB` table such as `t`, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
  p INT PRIMARY KEY,
  c INT,
  UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement on `t` succeeded on the master, since the rows affected are processed in the order determined by the `ORDER BY` option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

### Note

Every `NDB` table is implicitly partitioned by key when it is created. See [Section 17.2.5, “KEY Partitioning”](#), for more information.

**Restarting with `--initial`.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

**Replication from `NDB` to other storage engines.** It is possible to replicate an `NDB` table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the `NDB` storage engine for this to work).
- Using a storage engine does not perform binary logging for slave tables requires special handling.
- Use of a non-transactional storage engine for slave tables also requires special handling.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple masters not supported when replicating `NDB` to other storage engines.** For replication from `NDB` to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between MySQL Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between `NDB` and a different storage engine. (However, a MySQL Cluster database *can* simultaneously replicate to multiple slave MySQL Cluster databases.) If the master uses `NDB` tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to

change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

**Replicating NDB to a slave storage engine that does not perform binary logging.** If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `BINARY LOGGING NOT POSSIBLE ... STATEMENT CANNOT BE WRITTEN ATOMICALLY SINCE MORE THAN ONE ENGINE INVOLVED AND AT LEAST ONE ENGINE IS SELF-LOGGING` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0`.
- **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
- **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

### Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one MySQL Cluster to another. See [Replication and binary log filtering rules with replication between MySQL Clusters](#), for details.

**Replication from NDB to a nontransactional storage engine.** When replicating from NDB to a nontransactional storage engine such as `MyISAM`, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

In addition, when replicating from NDB to a storage engine that does not implement transactions, if the slave fails to apply any row changes from a given transaction, it does not roll back the rest of the transaction. (This is true when replicating tables using any transactional storage engine—not only NDB—to a nontransactional storage engine.) Because of this, it cannot be guaranteed that transactional consistency will be maintained on the slave in such cases.

**Replication and binary log filtering rules with replication between MySQL Clusters.** If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between MySQL Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see [Section 5.2.4, “The Binary Log”](#).

If you are replicating a MySQL Cluster to a slave that uses a storage engine other than [NDB](#), the considerations just given previously may not apply, as discussed elsewhere in this section.

**MySQL Cluster Replication and IPv6.** Currently, the NDB API and MGM API do not support IPv6. However, MySQL Servers—including those acting as SQL nodes in a MySQL Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between MySQL Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

However, all connections originating *within* the MySQL Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all MySQL Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.** MySQL Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in MySQL Cluster, see [Row-based replication: attribute promotion and demotion](#).

## 16.6.4. MySQL Cluster Replication Schema and Tables

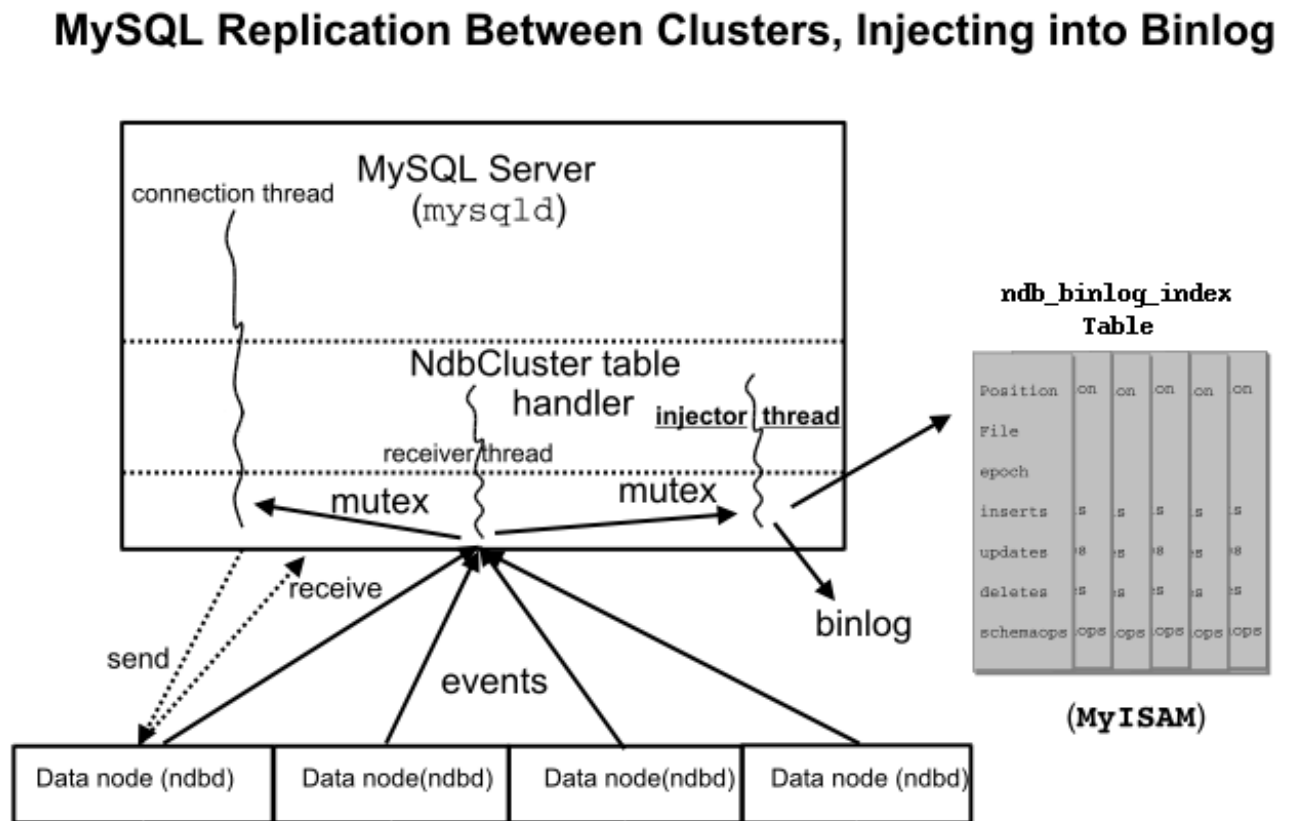

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses

the [MyISAM](#) storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
  `Position` BIGINT(20) UNSIGNED NOT NULL,
  `File` VARCHAR(255) NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `inserts` INT(10) UNSIGNED NOT NULL,
  `updates` INT(10) UNSIGNED NOT NULL,
  `deletes` INT(10) UNSIGNED NOT NULL,
  `schemaops` INT(10) UNSIGNED NOT NULL,
  `orig_server_id` INT(10) UNSIGNED NOT NULL,
  `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
  `gci` INT(10) UNSIGNED NOT NULL,
  PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
  `server_id` INT(10) UNSIGNED NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
  `start_pos` BIGINT(20) UNSIGNED NOT NULL,
  `end_pos` BIGINT(20) UNSIGNED NOT NULL,
)
```

```
PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

This table is populated only on slaves; on the master, no `DataMemory` is allocated to it. Since this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see [Replication and binary log filtering rules with replication between MySQL Clusters](#).

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the NDB binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See [Section 12.7.5.3, “SHOW BINLOG EVENTS Syntax”](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to NDB tables. It is defined as shown here:

```
CREATE TABLE ndb_schema (
  `db` VARBINARY(63) NOT NULL,
  `name` VARBINARY(63) NOT NULL,
  `slock` BINARY(32) NOT NULL,
  `query` BLOB NOT NULL,
  `node_id` INT UNSIGNED NOT NULL,
  `epoch` BIGINT UNSIGNED NOT NULL,
  `id` INT UNSIGNED NOT NULL,
  `version` INT UNSIGNED NOT NULL,
  `type` INT UNSIGNED NOT NULL,
  PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```
shell> ndb_show_tables -t 2
id  type      state  logging database  schema  name
4   UserTable Online  Yes      mysql     def     ndb_apply_status
5   UserTable Online  Yes      ndbworld  def     City
6   UserTable Online  Yes      ndbworld  def     Country
3   UserTable Online  Yes      mysql     def     NDB$BLOB_2_3
7   UserTable Online  Yes      ndbworld  def     CountryLanguage
2   UserTable Online  Yes      mysql     def     ndb_schema

NDBT_ProgramExit: 0 - OK
```

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='City' \G
***** 1. row *****
db: ndbworld
name: City
slock:
query: alter table City engine=ndb
node_id: 4
epoch: 0
id: 0
version: 0
type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.

## Note

When performing schema changes on NDB tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the `ndb_apply_status` table or the `ndb_schema` table does not exist on the slave, `ndb_restore` re-creates the missing table or tables (Bug #14612).

Conflict resolution for MySQL Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

## 16.6.5. Preparing the MySQL Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 16.6.2, “General Requirements for MySQL Cluster Replication”](#)).
2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'slave_user'@'slave_host'
-> IDENTIFIED BY 'slave_password';
```

In the previous statement, `slave_user` is the slave account user name, `slave_host` is the host name or IP address of the replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name “`myslave`,” logging in from the host named “`rep-slave`,” and using the password “`53cr37`,” use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'myslave'@'rep-slave'
-> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='master_host',
-> MASTER_PORT=master_port,
-> MASTER_USER='slave_user',
-> MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is “`rep-master`,” using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='rep-master',
-> MASTER_PORT=3306,
-> MASTER_USER='myslave',
-> MASTER_PASSWORD='53cr37';
```

For a complete list of clauses that can be used with this statement, see [Section 12.4.2.1, “CHANGE MASTER TO Syntax”](#).

You can also configure the slave to use the master by setting the corresponding startup options in the slave server's `my.cnf` file. To configure the slave in the same way as the preceding example `CHANGE MASTER TO` statement, the following information would need to be included in the slave's `my.cnf` file:

```
[mysqld]
master-host=rep-master
master-port=3306
```

```
master-user=myslave
master-password=53cr37
```

For additional options that can be set in `my.cnf` for replication slaves, see [Section 15.1.3, “Replication and Binary Logging Options and Variables”](#).

### Note

To provide replication backup capability, you will also need to add an `ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See [Section 16.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#), for details.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in [Section 16.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

### Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See [Section 15.1.2, “Replication Formats”](#).) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See [Section 16.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#), for information regarding the latter option.

## 16.6.6. Starting MySQL Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
--log-bin --binlog-format=ROW &
```

In the previous statement, `id` is this server's unique ID (see [Section 16.6.2, “General Requirements for MySQL Cluster Replication”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

### Note

You can also start the master with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters.

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the command just shown, *id* is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

### Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO
-> MASTER_LOG_FILE='',
-> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see [Section 16.6.8, “Implementing Failover with MySQL Cluster Replication”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 16.6.7, “Using Two Replication Channels for MySQL Cluster Replication”](#).

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

### Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON |
+-----+-----+
```

```

slave_compressed_protocol  OFF
slave_load_tmpdir          /tmp
slave_net_timeout          3600
slave_skip_errors          OFF
slave_transaction_retries  10
+-----+
6 rows in set (0.00 sec)

```

## 16.6.7. Using Two Replication Channels for MySQL Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Server ID	Description
1	Master - primary replication channel ( <i>M</i> )
2	Master - secondary replication channel ( <i>M'</i> )
3	Slave - primary replication channel ( <i>S</i> )
4	Slave - secondary replication channel ( <i>S'</i> )

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```

shellM> mysqld --ndbcluster --server-id=1 \
            --log-bin --binlog-format=row &

```

2. Start the secondary replication master:

```

shellM'> mysqld --ndbcluster --server-id=2 \
            --log-bin --binlog-format=row &

```

3. Start the primary replication slave server:

```

shellS> mysqld --ndbcluster --server-id=3 \
            --skip-slave-start &

```

4. Start the secondary replication slave:

```

shellS'> mysqld --ndbcluster --server-id=4 \
            --skip-slave-start &

```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```

mysqlS> START SLAVE;

```

### Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in [Section 16.6.8, “Implementing Failover with MySQL Cluster Replication”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

## 16.6.8. Implementing Failover with MySQL Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster as shown here:

```
mysqlM'> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

#### Note

`@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

#### Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from *M* to *S'*, or from *M'* to *S*; however, this has not yet been tested.

## 16.6.9. MySQL Cluster Backups With MySQL Cluster Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 16.6.5, “Preparing the MySQL Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

- **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the master cluster, and `port` is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

### Note

The port number needs to be specified only if the default port (1186) is not being used. See [Section 16.2.3, “Initial Configuration of MySQL Cluster”](#), for more information about ports and port allocation in MySQL Cluster.

In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellM> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see [Section 16.6.5, “Preparing the MySQL Cluster for Replication”](#)), this would be executed as follows:

```
shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It is necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

### Important

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

It is important to make sure that the slave's `apply_status` table does not contain any records prior to running the restore process. You can accomplish this by running this SQL statement on the slave:

```
mysqlS> DELETE FROM mysql.ndb_apply_status;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \
-b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in [Section 16.6, “MySQL Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
-r ./var/BACKUPS/BACKUP-1
```

### Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See [Section 16.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#).)

- Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in [Section 16.6.8, “Implementing Failover with MySQL Cluster Replication”](#)):

```
mysqlS> SELECT @latest:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

- Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

- Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

- Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 16.5.3, “Online Backup of MySQL Cluster”](#).

## 16.6.9.1. MySQL Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see [Section 16.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#)). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```

#!/user/bin/perl -w

}

# end reset-slave.pl

```

### 16.6.9.2. Point-In-Time Recovery Using MySQL Cluster Replication

*Point-in-time* recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of MySQL Cluster tables with MySQL Cluster and MySQL Cluster Replication can be accomplished using a native NDB data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of MySQL Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see [Section 16.5.3, “Online Backup of MySQL Cluster”](#)).
2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)
4. Locate the last known good backup.
5. Clear the data node file systems (using `ndbd --initial` or `ndbmtdd --initial`).

#### Note

MySQL Cluster Disk Data tablespace and log files are not removed by `--initial`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.
7. Execute `ndb_restore`, restoring all data. You must include the `--restore_epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See [Section 16.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#), for more information.)
8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.
9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

```
SELECT @LAST_EPOCH:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

```
SELECT Position, @FIRST_FILE:=File
FROM mysql.ndb_binlog_index
WHERE epoch > @LAST_EPOCH ORDER BY epoch ASC LIMIT 1;
```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).)

See also [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#), for more information about the binary log, replication, and incremental recovery.

## 16.6.10. MySQL Cluster Replication: Multi-Master and Circular Replication

It is possible to use MySQL Cluster in multi-master replication, including circular replication between a number of MySQL Clusters.

**Circular replication example.** In the next few paragraphs we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

### Important

You should execute the following statement before starting circular replication:

```
mysql> SET GLOBAL SLAVE_EXEC_MODE = 'IDEMPOTENT';
```

This is necessary to suppress duplicate-key and other errors that otherwise break circular replication in MySQL Cluster. `IDEMPOTENT` mode is also required for multi-master replication when using MySQL Cluster. (Bug #31609)

See `slave_exec_mode`, for more information.

**Using NDB-native backup and restore to initialize a slave MySQL Cluster.** When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one MySQL Cluster to create a backup and then applying this backup on another MySQL Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second MySQL Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

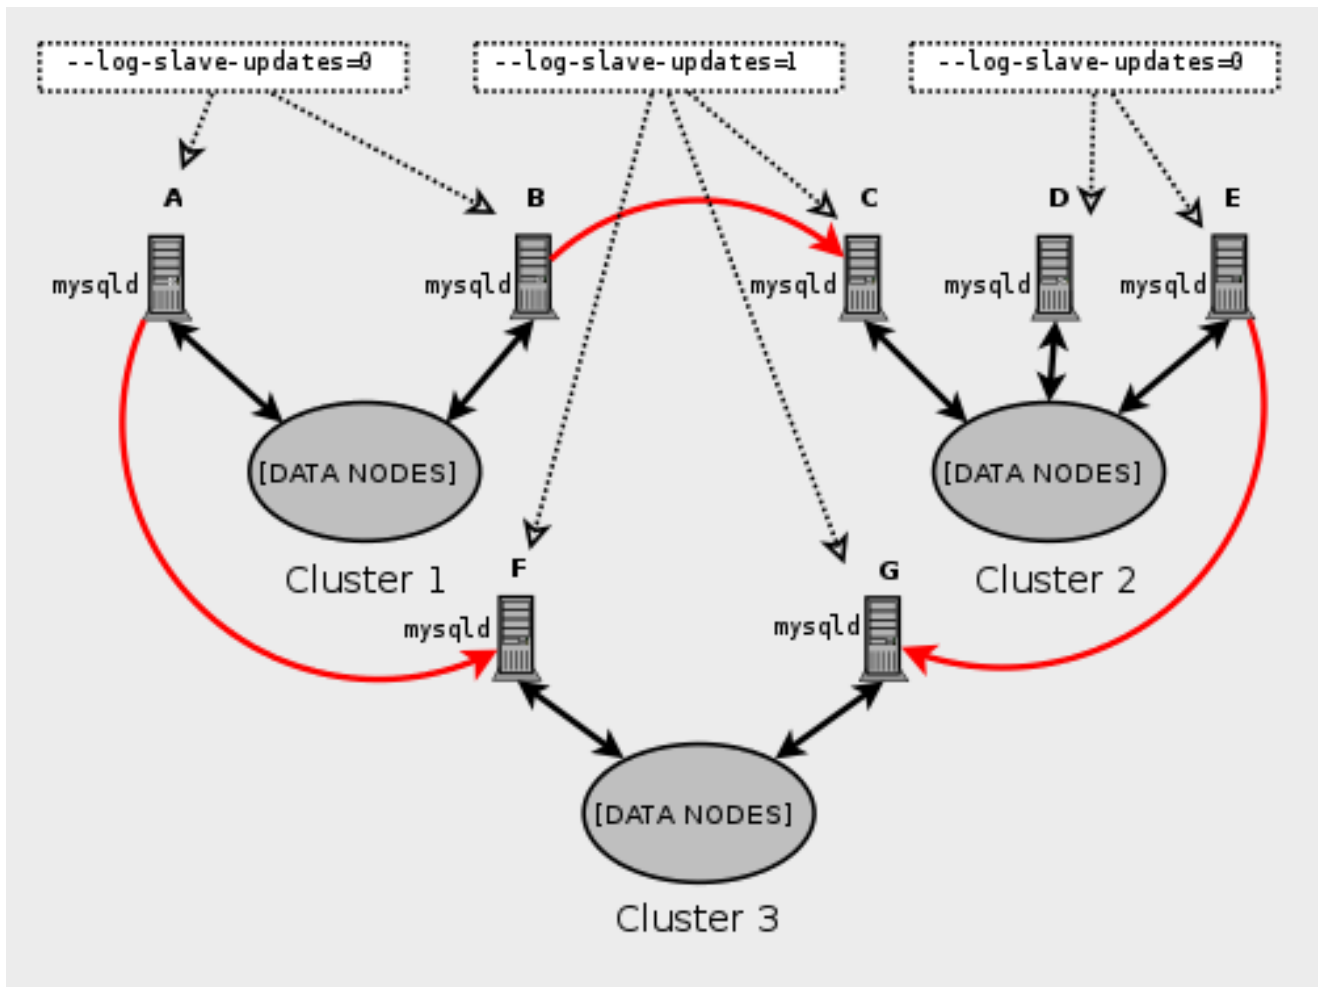

This is a known issue which we intend to address in a future release.

**Multi-master failover example.** In this section, we discuss failover in a multi-master MySQL Cluster replication setup with three MySQL Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given MySQL Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

MySQL servers acting as replication slaves must be run with the `--log-slave-updates` option. Which `mysqld` processes require this option is also shown in the preceding diagram.

### Note

Using the `--log-slave-updates` option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between MySQL Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status
-> WHERE server_id=1;

mysqlC> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE orig_epoch >= @latest
-> AND orig_server_id = 1
-> ORDER BY epoch ASC LIMIT 1;
```

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
-> MASTER_HOST = 'serverC'
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see [Section 12.4.2.1, “CHANGE MASTER TO Syntax”](#), and [Section 12.7.5.35, “SHOW SLAVE STATUS Syntax”](#).

## 16.6.11. MySQL Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update to the row on a given master should be applied on the slave.

Some types of conflict resolution supported by MySQL Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a “timestamp” column (although its type cannot be `TIMESTAMP`, as explained later in this section); epoch-based conflict resolution functions introduced in MySQL Cluster NDB 7.2.1 (`NDB$EPOCH()` and `NDB$EPOCH_TRANS()`) compare the order in which epochs are replicated. Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

### Important

Conflict resolution as described in this section is always applied on a row-by-row basis rather than a transactional basis. In addition, it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

**Requirements.** Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:

- On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see [The `ndb\_replication` system table](#)).

### Note

If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

See [Section 15.4.1.17, “Replication and `max\_allowed\_packet`”](#), for more information about this issue.

- On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see [The `ndb\_replication` system table](#)).

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT` (`INTEGER`) or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary MySQL Cluster, and do not make use of timestamps.

**Master column control.** We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master's binary log. This is done with the `--ndb-log-update-as-write` option for

`mysqld`, as described later in this section.

### Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

## Logging Full or Partial Rows (`--ndb-log-updated-only` Option)

Command-Line Format	<code>--ndb-log-updated-only</code>	
Option-File Format	<code>ndb_log_updated_only</code>	
Variable Name	<code>ndb_log_updated_only</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to 0 or OFF.

## `--ndb-log-update-as-write` Option: Logging Changed Data as Updates

Command-Line Format	<code>--ndb-log-update-as-write</code>	
Option-File Format	<code>ndb-log-update-as-write</code>	
Variable Name	<code>ndb_log_update_as_write</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.) To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

**Conflict resolution control.** Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

**The `ndb_replication` system table.** To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple mas-

ter-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
  PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the next few paragraphs.

**db.** The name of the database containing the table to be replicated.

**table\_name.** The name of the table to be replicated.

**server\_id.** The unique server ID of the MySQL instance (SQL node) where the table resides.

**binlog\_type.** The type of binary logging to be employed. This is determined as shown in the following table:

Value	Internal Value	Description
0	NBT_DEFAULT	Use server default
1	NBT_NO_LOGGING	Do not log this table in the binary log
2	NBT_UPDATED_ONLY	Only updated attributes are logged
3	NBT_FULL	Log full row, even if not updated (MySQL server default behavior)
4	NBT_USE_UPDATE	(For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only—not intended for separate use)
5	[Not used]	---
6	NBT_UPDATED_ONLY_USE_UPDATE (equal to NBT_UPDATED_ONLY   NBT_USE_UPDATE)	Use updated attributes, even if values are unchanged
7	NBT_FULL_USE_UPDATE (equal to NBT_FULL   NBT_USE_UPDATE)	Use full row, even if values are unchanged

**conflict\_fn.** The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- `NDB$OLD(column_name)`
- `NDB$MAX(column_name)`
- `NDB$MAX_DELETE_WIN(column_name)`
- `NDB$EPOCH( )` (MySQL Cluster NDB 7.2.1 and later)
- `NDB$EPOCH_TRANS( )` (MySQL Cluster NDB 7.2.1 and later)
- `NULL`

These functions are described in the next few paragraphs.

**NDB\$OLD(column\_name).** If the value of `column_name` is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (master_old_column_value == slave_current_column_value)
  perform_update();
else
  log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

### Important

The column value from the master’s “before” image is used by this function.

**NDB\$MAX(*column\_name*)**. If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```
if (master_new_column_value > slave_current_column_value)
    perform_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

### Important

The column value from the master’s “after” image is used by this function.

**NDB\$MAX\_DELETE\_WIN(*column\_name*)**. This is a variation on **NDB\$MAX()**. Due to the fact that no timestamp is available for a delete operation, a delete using **NDB\$MAX()** is in fact processed as **NDB\$SOLD**. However, for some use cases, this is not optimal. For **NDB\$MAX\_DELETE\_WIN()**, if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```
if ( (master_new_column_value > slave_current_column_value)
    ||
    operation.type == "delete")
    perform_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

### Note

As with **NDB\$MAX()**, the column value from the master’s “after” image is the value used by this function.

**NDB\$EPOCH()**. The **NDB\$EPOCH()** function, available beginning with MySQL Cluster NDB 7.2.1, tracks the order in which replicated epochs are applied on a slave MySQL Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of **NDB\$EPOCH()** also applies to **NDB\$EPOCH\_TRANS()**. Any exceptions are noted in the text.

**NDB\$EPOCH()** is asymmetric, operating on one MySQL Cluster in a two-cluster circular replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible for detecting and handling conflicts, while the slave on the secondary is not involved in any conflict detection or handling.

When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary MySQL Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary MySQL Cluster always wins any conflicts with the secondary—that is, that the primary’s changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.

- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.
- Assuming a period of sufficient length without any conflicts, all data on the secondary MySQL Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than

```
CEIL( LOG2( TimeBetweenGlobalCheckpoints / TimeBetweenEpochs ), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints`, `TimeBetweenEpochs`, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exception table schema rules as described elsewhere in this section (see `NDB$OLD(column_name)`). Note that you need to create any exception table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are activated by including relevant entries in the `mysql.ndb_replication` table (see [The ndb\\_replication system table](#)). The roles of the primary and secondary MySQL Clusters in this scenario are fully determined by `mysql.ndb_replication` table entries.

### Note

Because the conflict detection algorithms employed by `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are asymmetric, you must use different values for the primary slave's and secondary slave's `server_id` entries.

**`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` status variables.** MySQL Cluster NDB 7.2.1 introduces several status variables that can be used to monitor `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this slave was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

`Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`; the number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

For more information, see [Section 16.3.4.4, “MySQL Cluster Status Variables”](#).

**Limitations on `NDB$EPOCH()`.** The following limitations currently apply when using `NDB$EPOCH()` to perform conflict detection:

- Conflicts are detected using MySQL Cluster epoch boundaries, with granularity proportional to `TimeBetweenEpochs` (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to  $2 * (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})$ . This implies that—assuming the default for `TimeBetweenEpochs` and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.
- Additional storage is required for tables using the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.
- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two MySQL Clusters in a circular “active-active” configuration are currently supported when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` for conflict detection.
- Tables having `BLOB` or `TEXT` columns are not currently supported with `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`.

**`NDB$EPOCH_TRANS()`.** `NDB$EPOCH_TRANS()` extends the `NDB$EPOCH()` function, and, like `NDB$EPOCH()`, is available beginning with MySQL Cluster NDB 7.2.1. Conflicts are detected and handled in the same way using the “primary wins all” rule (see `NDB$EPOCH()`) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where `NDB$EPOCH()` realigns individual conflicting rows on the secondary, `NDB$EPOCH_TRANS()` realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that Version 2 binary log row events are used (`--log-bin-use-v1-row-events` equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all transaction IDs must be recorded in the secondary's binary log (`--ndb-log-transaction-id` option), which adds a further variable overhead (up to 13 bytes per row).

See `NDB$EPOCH()`.

**`NULL`.** Indicates that conflict resolution is not to be used for the corresponding table.

**Status information.** A server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

**Exceptions table.** To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` in MySQL Cluster NDB 7.2.1 and later. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exception table name should be `mytable$EX`.) This table is created as follows:

```
CREATE TABLE original_table$EX (
  server_id INT UNSIGNED,
  master_server_id INT UNSIGNED,
  master_epoch BIGINT UNSIGNED,
  count INT UNSIGNED,
  original_table_pk_columns,
  [additional_columns,]
  PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

The first four columns are required. Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table.

### Note

The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `master_server_id`, `master_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

The data types for the columns duplicating the primary key columns of the original table should be the same as for (or larger than) the original columns.

Additional columns may optionally be defined following these columns, but not before any of them; any such extra columns cannot be `NOT NULL`. The exception table's primary key must be defined as shown. The exception table must use the `NDB` storage engine. An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.

### Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

**Examples.** The following examples assume that you have already a working MySQL Cluster replication setup, as described in [Section 16.6.5, “Preparing the MySQL Cluster for Replication”](#), and [Section 16.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#).

- **`NDB$MAX()` example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.
2. On the master, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
  columns
  mycol INT UNSIGNED,
  columns
) ENGINE=NDB;
```

Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the slave.

### Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE` should be used to control logging on the master using the `ndb_replication` table rather than by using command-line options.

- **`NDB$OLD()` example.** Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```
CREATE TABLE test.t2 (
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  columns,
  mycol INT UNSIGNED NOT NULL,
  columns,
  PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX (
  server_id SMALLINT UNSIGNED,
  master_server_id INT UNSIGNED,
  master_epoch BIGINT UNSIGNED,
  count BIGINT UNSIGNED,
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  [additional_columns,]
  PRIMARY KEY(server_id, master_server_id, master_epoch, count)
)
ENGINE=NDB;
```

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

## 16.7. Changes in MySQL Cluster

This section contains changelog information for MySQL Cluster releases that use version 7.2 or newer of the `NDBCLUSTER` storage engine, starting with MySQL Cluster NDB 7.2.1.

Each MySQL Cluster NDB 7.2 release, starting with MySQL Cluster NDB 7.2.1, is based on a mainline MySQL Server 5.5 release and a particular version of the `NDBCLUSTER` storage engine, as shown in the version string returned by executing `SELECT VERSION()` in the `mysql` client, or by executing the `ndb_mgm` client `SHOW` or `STATUS` command; for more information, see [Chapter 16, MySQL Cluster NDB 7.2](#).

For general information about features added in MySQL Cluster, see [Section 16.1.4, “MySQL Cluster Development History”](#). For a complete list of all bugfixes and feature changes in MySQL Cluster, please refer to the changelog section for each individual MySQL Cluster release.

An overview of features added in MySQL 5.5 not specific to MySQL Cluster can be found here: [Section 1.4, “What Is New in MySQL 5.5”](#). For a complete list of all bugfixes and features changes made in MySQL 5.5 that are not specific to MySQL Cluster, see [Section D.1, “Changes in Release 5.5.x \(Production\)”](#).

This section contains changelogs for individual MySQL Cluster NDB 7.2 releases, beginning with MySQL Cluster NDB 7.2.1.

### 16.7.1. Changes in MySQL Cluster NDB 7.2

This section contains change history information for MySQL Cluster NDB 7.2.1 and later MySQL Cluster releases based on version 7.2 of the `NDBCLUSTER` storage engine, currently in development.

#### Note

MySQL Cluster NDB 7.2.0 was based on MySQL 5.1. For more information, see [MySQL Cluster Development in MySQL Cluster NDB 7.2.1](#).

For an overview of new features added in MySQL Cluster NDB 7.2, see [MySQL Cluster Development in MySQL Cluster NDB 7.2.1](#).

#### 16.7.1.1. Changes in MySQL Cluster NDB 7.2.5 (5.5.20-ndb-7.2.5) (Not yet released)

MySQL Cluster NDB 7.2.5 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine for testing and user feedback.

**Obtaining MySQL Cluster NDB 7.2.** MySQL Cluster NDB 7.2.5 source code and binaries can be obtained from <http://dev.mysql.com/downloads/cluster/>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.5 through MySQL 5.5.20 (see [Section D.1.3, “Changes in MySQL 5.5.20 \(10 January 2012\)”](#)).

## Bugs Fixed

- **Important Change:** A number of changes have been made in the configuration of transporter send buffers.
  1. The data node configuration parameter `ReservedSendBufferMemory` is now deprecated, and thus subject to removal in a future MySQL Cluster release. `ReservedSendBufferMemory` has been non-functional since it was introduced and remains so.
  2. `TotalSendBufferMemory` now works correctly with data nodes using `ndbmtl`.
  3. `SendBufferMemory` can now over-allocate into `SharedGlobalMemory` for `ndbmtl` data nodes (only).
  4. A new data node configuration parameter `ExtraSendBufferMemory` is introduced. Its purpose is to control how much additional memory can be allocated to the send buffer over and above that specified by `TotalSendBufferMemory` or `SendBufferMemory`. The default setting (0) allows up to 16MB to be allocated automatically.

(Bug #13633845, Bug #11760629, Bug #53053)

- **Cluster Replication: Important Change:** The master limited the number of operations per transaction to 10000 (based on `TimeBetweenEpochs`). This could result in a larger number of data-modification operations in a single epoch than could be applied at one time, due to the limit imposed on the slave by its (own) setting for `MaxDMLOperationsPerTransaction`.

The fix for this issue is to allow a replication slave cluster to exceed the configured value of `MaxDMLOperationsPerTransaction` when necessary, so that it can apply all DML operations received from the master in the same transaction. (Bug #12825405)

- A data node crashed when more than 16G fixed-size memory was allocated by `DBTUP` to one fragment (because the `DBACC` kernel block was not prepared to accept values greater than 32 bits from it, leading to an overflow). Now in such cases, the data node returns Error 889 `TABLE FRAGMENT FIXED DATA REFERENCE HAS REACHED MAXIMUM POSSIBLE VALUE...`. When this happens, you can work around the problem by increasing the number of partitions used by the table (such as by using the `MAXROWS` option with `CREATE TABLE`). (Bug #13637411)

References: See also Bug #11747870, Bug #34348.

- A very large value for `BackupWriteSize`, as compared to `BackupMaxWriteSize`, `BackupDataBufferSize`, or `role="ndbparam:ndbd" BackupLogBufferSize`, could cause a local checkpoint or backup to hang. (Bug #13613344)
- To avoid TCP transporter overload, an overload flag is kept in the NDB kernel for each data node; this flag is used to abort key requests if needed, yielding error 1218 `SEND BUFFERS OVERLOADED IN NDB KERNEL` in such cases. Scans can also put significant pressure on transporters, especially where scans with a high degree of parallelism are executed in a configuration with relatively small send buffers. However, in these cases, overload flags were not checked, which could lead to node failures due to send buffer exhaustion. Now, overload flags are checked by scans, and in cases where returning sufficient rows to match the batch size (`-ndb-batch-size` server option) would cause an overload, the number of rows is limited to what can be accommodated by the send buffer.

See also [Section 16.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”](#). (Bug #13602508)

- A node failure and recovery while performing a scan on more than 32 partitions led to additional node failures during node takeover. (Bug #13528976)

## 16.7.1.2. Changes in MySQL Cluster NDB 7.2.4 (5.5.19-ndb-7.2.4) (15 February 2012, General Availability)

MySQL Cluster NDB 7.2.4 is the first *General Availability* release in the MySQL Cluster NDB 7.2 release series, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.2 development releases.

**Obtaining MySQL Cluster NDB 7.2.** MySQL Cluster NDB 7.2.4 source code and binaries can be obtained from <http://dev.mysql.com/downloads/cluster/>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.5 through MySQL 5.5.19 (see [Section D.1.4, “Changes in MySQL 5.5.19 \(08 December 2011\)”](#)).

### Functionality Added or Changed

- **Important Change:** A `mysqld` process joining a MySQL Cluster where distributed privileges are in use now automatically executes a `FLUSH PRIVILEGES` as part of the connection process, so that the cluster's distributed privileges take immediate effect on the new SQL node. (Bug #13340854)

### Bugs Fixed

- At the beginning of a local checkpoint, each data node marks its local tables with a “to be checkpointed” flag. A failure of the master node during this process could cause either the LCP to hang, or one or more data nodes to be forcibly shut down. (Bug #13436481)
- A node failure while a `ANALYZE TABLE` statement was executing resulted in a hung connection (and the user was not informed of any error that would cause this to happen). (Bug #13416603)

References: See also Bug #13407848.

- **Cluster Replication:** Under certain circumstances, the `Rows` count in the output of `SHOW TABLE STATUS` for a replicated slave `NDB` table could be misreported as many times larger than the result of `SELECT COUNT ( * )` on the same table. (Bug #13440282)

## 16.7.1.3. Changes in MySQL Cluster NDB 7.2.3 (5.5.17-ndb-7.2.3) (Not released)

MySQL Cluster NDB 7.2.3 is a new development preview release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine for testing and user feedback.

**Obtaining MySQL Cluster NDB 7.2.** MySQL Cluster NDB 7.2.3 source code and binaries can be obtained from <http://dev.mysql.com/downloads/cluster/>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.5 through MySQL 5.5.17 (see [Section D.1.6, “Changes in MySQL 5.5.17 \(19 October 2011\)”](#)).

### Functionality Added or Changed

- Added the `ThreadConfig` data node configuration parameter to enable control of multiple threads and CPUs when using `ndb-mtd`, by assigning threads of one or more specified types to execute on one or more CPUs. This can provide more precise and flexible control over multiple threads than can be obtained using the `LockExecuteThreadToCPU` parameter. (Bug #11795581)

### Bugs Fixed

- **Cluster Replication: Important Change:** A unique key constraint violation caused `NDB` slaves to stop rather than to continue when the `slave_exec_mode` was `IDEMPOTENT`. In such cases, `NDB` now behaves as other MySQL storage engines do when in `IDEMPOTENT` mode. (Bug #11756310)
- Added the `MinFreePct` data node configuration parameter, which specifies a percentage of data node resources to hold in reserve for restarts. The resources monitored are `DataMemory`, `IndexMemory`, and any per-table `MAX_ROWS` settings (see [Section 12.1.17, “CREATE TABLE Syntax”](#)). The default value of `MinFreePct` is 5, which means that 5% from each these resources is now set aside for restarts. (Bug #13436216)
- Issuing `TRUNCATE TABLE` on `mysql.user`, `mysql.host`, `mysql.db`, `mysql.tables_priv`, `mysql.proxies_priv`, or `mysql.procs_priv`, when these tables had been converted to MySQL Cluster distributed grant tables, caused `mysqld` to crash. (Bug #13346955)
- Restarting an SQL node configured for distributed grants could sometimes result in a crash. (Bug #13340819)
- Previously, forcing simultaneously the shutdown of multiple data nodes using `SHUTDOWN -F` in the `ndb_mgm` management client could cause the entire cluster to fail. Now in such cases, any such nodes are forced to abort immediately. (Bug #12928429)
- **Cluster Replication:** With many SQL nodes, all writing binary logs, connected to a MySQL Cluster, `RENAME TABLE` could cause

data node processes ([ndbmt\\_d](#)) to fail. (Bug #13447705)

#### 16.7.1.4. Changes in MySQL Cluster NDB 7.2.2 (5.5.16-ndb-7.2.2) (14 December 2011, Development Milestone)

MySQL Cluster NDB 7.2.2 is a new development preview release of MySQL Cluster, incorporating new features in the [NDBCLUSTER](#) storage engine for testing and user feedback.

**Obtaining MySQL Cluster NDB 7.2.** MySQL Cluster NDB 7.2.2 source code and binaries can be obtained from <http://dev.mysql.com/downloads/cluster/>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.5 through MySQL 5.5.16 (see [Section D.1.7, “Changes in MySQL 5.5.16 \(15 September 2011\)”](#)).

##### Functionality Added or Changed

- **Cluster API:** Added support for the Memcache API using *ndbmemcache*, a loadable storage engine for memcached version 1.6 and later, which can be used to provide a persistent MySQL Cluster data store, accessed using the memcache protocol.

The standard [memcached](#) caching engine is now included in the MySQL Cluster distribution. Each [memcached](#) server, in addition to providing direct access to data stored in a MySQL Cluster, is able to cache data locally and serve (some) requests from this local cache.

The [memcached](#) server can also provide an interface to existing MySQL Cluster tables that is strictly defined, so that an administrator can control exactly which tables and columns are referenced by particular memcache keys and values, and which operations are allowed on these keys and values.

For more information see [Section 16.5.15, “ndbmemcache”](#).

##### Bugs Fixed

- The [include/storage](#) directory, where the header files supplied for use in compiling MySQL Cluster applications are normally located, was missing from MySQL Cluster release packages for Windows. (Bug #12690665)

#### 16.7.1.5. Changes in MySQL Cluster NDB 7.2.1 (5.5.15-ndb-7.2.1) (03 October 2011, Development Milestone)

MySQL Cluster NDB 7.2.1 is a new development preview release of MySQL Cluster, incorporating new features in the [NDBCLUSTER](#) storage engine for testing and user feedback.

**Obtaining MySQL Cluster NDB 7.2.** MySQL Cluster NDB 7.2.1 source code and binaries can be obtained from <http://dev.mysql.com/downloads/cluster/>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.5 through MySQL 5.5.15 (see [Section D.1.8, “Changes in MySQL 5.5.15 \(28 July 2011\)”](#)).

##### Functionality Added or Changed

- **Performance:** Added support for pushing down joins to the NDB kernel for parallel execution across the data nodes, which can speed up execution of joins across [NDB](#) tables by a factor of 20 or more in some cases. Some restrictions apply on the types of joins that can be optimized in this way; in particular, columns to be joined must use exactly the same data type, and cannot be any of the [BLOB](#) or [TEXT](#) types. In addition, columns to be joined must be part of a table index or primary key. Support for this feature can be enabled or disabled using the [ndb\\_join\\_pushdown](#) server system variable (enabled by default); see the description of this variable for more information and examples.

As part of this improvement, the status variables [Ndb\\_pushed\\_queries\\_defined](#), [Ndb\\_pushed\\_queries\\_dropped](#), [Ndb\\_pushed\\_queries\\_executed](#), and [Ndb\\_pushed\\_reads](#) also been introduced for monitoring purposes. You can also

see whether a given join is pushed down using [EXPLAIN](#). In addition, several new counters relating to push-down join performance have been added to the [counters](#) table in the [ndbinfo](#) database. For more information, see the descriptions of the status variables previously mentioned.

- **Important Change:** The default values for a number of MySQL Cluster data node configuration parameters have changed, to provide more resiliency to environmental issues and better handling of some potential failure scenarios, and to perform more reliably with increases in memory and other resource requirements brought about by recent improvements in join handling by [NDB](#). The affected parameters are listed here:
  - [HeartbeatIntervalDbDb](#): Default increased from 1500 ms to 5000 ms.
  - [ArbitrationTimeout](#): Default increased from 3000 ms to 7500 ms.
  - [TimeBetweenEpochsTimeout](#): Now effectively disabled by default (default changed from 4000 ms to 0).
  - [SharedGlobalMemory](#): Default increased from 20MB to 128MB.
  - [MaxParallelScansPerFragment](#): Default increased from 32 to 256.

In addition, when [MaxNoOfLocalScans](#) is not specified, the value computed for it automatically has been increased by a factor of 4 (that is, to 4 times [MaxNoOfConcurrentScans](#), times the number of data nodes in the cluster).

- **Important Change:** MySQL user privileges can now be distributed automatically across all MySQL servers (SQL nodes) connected to the same MySQL Cluster. Previously, each MySQL Server's user privilege tables were required to use the [MyISAM](#) storage engine, which meant that a user account and its associated privileges created on one SQL node were not available on any other SQL node without manual intervention. MySQL Cluster now provides an SQL script file [ndb\\_dist\\_priv.sql](#) that can be found in [share/mysql](#) under the MySQL installation directory; loading this script creates a stored procedure [mysql\\_cluster\\_move\\_privileges](#) that can be used following initial installation to convert the privilege tables to the [NDB](#) storage engine, so that any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Note that you may need to execute [FLUSH PRIVILEGES](#) on any SQL nodes with connected MySQL clients (or to disconnect and then reconnect the clients) in order for those clients to be able to see the changes in privileges.

Once [mysql\\_cluster\\_move\\_privileges](#) has been executed successfully, all MySQL user privileges are distributed across all connected MySQL Servers. MySQL Servers that join the cluster after this automatically participate in the privilege distribution.

[ndb\\_dist\\_priv.sql](#) also provides stored routines that can be used to verify that the privilege tables have been distributed successfully, and to perform other tasks.

For more information, see [Section 16.5.13, “Distributed MySQL Privileges for MySQL Cluster”](#).

- **Cluster Replication: Important Change:** Due to the existing layout of binary log row events, it was not possible to extend them with extra information which could be safely ignored by old slaves. New versions of the [WRITE\\_ROW](#), [UPDATE\\_ROW](#), and [DELETE\\_ROW](#) events have been implemented; these are referred to as “Version 2” binary log events, and are intended for future enhancements such as improved conflict detection and resolution. The [TABLE\\_MAP](#) event is not affected.

Version 2 binary log row events are not backward compatible, and cannot be read by older slaves. A new [mysqld](#) option [--log-bin-use-v1-row-events](#) can be used to force writing of Version 1 row events into the binary log. This can be used during upgrades to make a newer [mysqld](#) generate Version 1 binary log row events that can be read by older slaves.

- **Important Change:** By default, data nodes now exhibit fail-fast behavior whenever they encounter corrupted tuples—in other words, a data node forcibly shuts down whenever it detects a corrupted tuple. To override this behavior, you can disable the [CrashOnCorruptedTuple](#) data node configuration parameter, which is enabled by default.

This is a change from MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, where [CrashOnCorruptedTuple](#) was disabled (so that data nodes ignored tuple corruption) by default. (Bug #12598636)

- It is now possible to filter the output from [ndb\\_config](#) so that it displays only system, data node, or connection parameters and values, using one of the options [--system](#), [--nodes](#), or [--connections](#), respectively. In addition, it is now possible to specify from which data node the configuration data is obtained, using the [--config\\_from\\_node](#) option that is added in this release.

For more information, see [Section 16.4.6, “ndb\\_config — Extract MySQL Cluster Configuration Information”](#). (Bug #11766870)

- **Cluster Replication:** Added two new conflict detection functions [NDB\\$EPOCH\(\)](#) and [NDB\\$EPOCH\\_TRANS\(\)](#) useful in circular

replication scenarios with two MySQL Clusters. Each of these functions requires designating one cluster as primary and one as secondary, and implements a “primary always wins” rule for determining whether to accept conflicting changes. When using `NDB$EPOCH()`, conflicting rows on the secondary are realigned with those on the primary; when using `NDB$EPOCH_TRANS()`, it is transactions containing rows in conflict (and any transactions which depend on them) on the secondary that are realigned.

Using `NDB$EPOCH_TRANS()` as the conflict detection function has two additional requirements:

1. The binary log must be written using Version 2 row events; that is, the `mysqld` processes on both the primary and the secondary must be started with `--log-bin-use-v1-row-events=0`.
2. The secondary must include transaction IDs for all rows written into its binary log. This can be done by setting `--ndb-log-transaction-id=1`. (This server option is also added in this release.)

A number of new server status variables have been added to monitor conflict detection and resolution performed using these functions, including `Ndb_conflict_fn_epoch`, `Ndb_conflict_fn_epoch_trans`, and `Ndb_conflict_trans_row_conflict_count`. See [Section 16.3.4.4, “MySQL Cluster Status Variables”](#).

For more information, see [Section 16.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

### Bugs Fixed

- **Cluster API: Incompatible Change:** Restarting a machine hosting data nodes, SQL nodes, or both, caused such nodes when restarting to time out while trying to obtain node IDs.

As part of the fix for this issue, the behavior and default values for the NDB API `Ndb_cluster_connection::connect()` method have been improved. Due to these changes, the version number for the included NDB client library (`libndbclient.so`) has been increased from 4.0.0 to 5.0.0. For NDB API applications, this means that as part of any upgrade, you must do both of the following:

- Review and possibly modify any NDB API code that uses the `connect()` method, in order to take into account its changed default retry handling.
- Recompile any NDB API applications using the new version of the client library.

Also in connection with this issue, the default value for each of the two `mysqld` options `--ndb-wait-connected` and `--ndb-wait-setup` has been increased to 30 seconds (from 0 and 15, respectively). In addition, a hard-coded 30-second delay was removed, so that the value of `--ndb-wait-connected` is now handled correctly in all cases. (Bug #12543299)

- `AUTO_INCREMENT` values were not set correctly for `INSERT IGNORE` statements affecting NDB tables. This could lead such statements to fail with `GOT ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER` when inserting multiple rows containing duplicate values. (Bug #11755237, Bug #46985)

17.5.1. Partitioning Keys, Primary Keys, and Unique Keys .....	2009
17.5.2. Partitioning Limitations Relating to Storage Engines .....	2012
17.5.3. Partitioning Limitations Relating to Functions .....	2012

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by means of a [SHOW VARIABLES](#) statement such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';
```

Variable_name	Value
have_partitioning	YES

```
1 row in set (0.00 sec)
```

You can also check the output of the [SHOW PLUGINS](#) statement, as shown here:

```
mysql> SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	GPL
<b>partition</b>	<b>ACTIVE</b>	<b>STORAGE ENGINE</b>	<b>NULL</b>	<b>GPL</b>
ARCHIVE	ACTIVE	STORAGE ENGINE	NULL	GPL
BLACKHOLE	ACTIVE	STORAGE ENGINE	NULL	GPL
CSV	ACTIVE	STORAGE ENGINE	NULL	GPL
FEDERATED	DISABLED	STORAGE ENGINE	NULL	GPL
MEMORY	ACTIVE	STORAGE ENGINE	NULL	GPL
InnoDB	ACTIVE	STORAGE ENGINE	NULL	GPL
MRG_MYISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
MyISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
ndbcluster	DISABLED	STORAGE ENGINE	NULL	GPL

```
11 rows in set (0.00 sec)
```

If you do not see the [have\\_partitioning](#) variable with the value [YES](#) listed in the output of an appropriate [SHOW VARIABLES](#) statement, or if you do not see the [partition](#) plugin listed with the value [ACTIVE](#) for the [Status](#) column in the output of [SHOW PLUGINS](#) (show in bold text in the example just given), then your version of MySQL was not built with partitioning support.

MySQL 5.5 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in commercial MySQL Server binaries, see *MySQL Enterprise Server 5.1* on the MySQL Web site at <http://www.mysql.com/products/enterprise/server.html>.

To enable partitioning if you are compiling MySQL 5.5 from source, the build must be configured with the -

`DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see [Section 2.9, “Installing MySQL from Source”](#).

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option, in which case the value of `have_partitioning` is `DISABLED`. However, if you do this, you cannot access any partitioned tables until the server is once again restarted without the `--skip-partition` option.

An introduction to partitioning and partitioning concepts may be found in [Section 17.1, “Overview of Partitioning in MySQL”](#).

MySQL supports several types of partitioning, which are discussed in [Section 17.2, “Partitioning Types”](#), as well as subpartitioning, which is described in [Section 17.2.6, “Subpartitioning”](#).

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in [Section 17.3, “Partition Management”](#).

Table maintenance commands for use with partitioned tables are discussed in [Section 17.3.3, “Maintenance of Partitions”](#).

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 19.13, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 17.2.7, “How MySQL Partitioning Handles NULL”](#).

For known issues with partitioning in MySQL 5.5, see [Section 17.5, “Restrictions and Limitations on Partitioning”](#).

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.5 binaries are available from <http://dev.mysql.com/downloads/mysql/5.5.html>. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see [Section 2.9, “Installing MySQL from Source”](#). If you have problems compiling a partitioning-enabled MySQL 5.5 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

## 17.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.5.

For information on partitioning restrictions and feature limitations, see [Section 17.5, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 7.11.3.1, “Using Symbolic Links”](#), for an explanation of how this is done).

*Partitioning* takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of [RANGE](#), [LIST](#), and [\[LINEAR\] HASH](#) partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either [NULL](#) or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

([MAXVALUE](#) is used to represent the least upper bound for the type of integer in question. [-MAXVALUE](#) represents the greatest lower bound.)

For [\[LINEAR\] KEY](#), [RANGE COLUMNS](#), and [LIST COLUMNS](#) partitioning, the partitioning expression consists of a list of one or more columns.

For [\[LINEAR\] KEY](#) partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see [Section 17.2, “Partitioning Types”](#), as well as [Section 12.1.17, “CREATE TABLE Syntax”](#), which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see [Section 17.5.3, “Partitioning Limitations Relating to Functions”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.5 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.5.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see [Chapter 17, Partitioning](#).

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.5, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use [MyISAM](#) for one partition and [InnoDB](#) for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the [MERGE](#), [CSV](#), or [FEDERATED](#) storage engines.

Partitioning by [KEY](#) or [LINEAR KEY](#) is possible with [NDBCLUSTER](#), but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an [NDBCLUSTER](#) table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the [PARTITION BY KEY](#) or [PARTITION BY LINEAR KEY](#) clause of the [CREATE TABLE](#) or [ALTER TABLE](#) statement used to create or modify a user-partitioned [NDBCLUSTER](#) table, then the table is not required to have an explicit primary key. For more information, see [Section 16.1.6.1, “Noncompliance with SQL Syntax in MySQL Cluster”](#).

To employ a particular storage engine for a partitioned table, it is necessary only to use the [\[STORAGE\] ENGINE](#) option just as you would for a nonpartitioned table. However, you should keep in mind that [\[STORAGE\] ENGINE](#) (and other table options) need to be listed *before* any partitioning options are used in a [CREATE TABLE](#) statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the [InnoDB](#) storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

Each [PARTITION](#) clause can include a [\[STORAGE\] ENGINE](#) option, but in MySQL 5.5 this has no effect.

### Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options have no effect when defining partitions for tables using the `InnoDB` storage engine.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions on Windows. These options are ignored on Windows, except that a warning is generated.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The `MAX_ROWS` option can be useful for causing MySQL Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see [Section 17.4, “Partition Pruning”](#).

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as MySQL Partitioning development continues.

## 17.2. Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.5. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 17.2.1, “RANGE Partitioning”](#). MySQL 5.5 adds an extension, `RANGE COLUMNS`, to this type. See [Section 17.2.3.1, “RANGE COLUMNS partitioning”](#).
- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 17.2.2, “LIST Partitioning”](#). MySQL 5.5 adds an extension, `LIST COLUMNS`, to this type. See [Section 17.2.3.2, “LIST COLUMNS partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See [Section 17.2.4, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this

type, [LINEAR KEY](#), is also available. See [Section 17.2.5, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.5. However, it is not difficult in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 5.5, it is also possible to use a [DATE](#) or [DATETIME](#) column as the partitioning column using [RANGE COLUMNS](#) and [LIST COLUMNS](#) partitioning.

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or [NULL](#). If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- [Section 17.2.1, “RANGE Partitioning”](#)
- [Section 17.2.4, “HASH Partitioning”](#)
- [Section 17.2.4.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see the following sections:

- [Section 17.4, “Partition Pruning”](#)
- [Section 17.2.6, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the [TO\\_DAYS\(\)](#), [YEAR\(\)](#), and [TO\\_SECONDS\(\)](#) functions. However, you can use other date and time functions that return an integer or [NULL](#), such as [WEEKDAY\(\)](#), [DAYOFYEAR\(\)](#), or [MONTH\(\)](#). See [Section 11.7, “Date and Time Functions”](#), for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the [RANGE](#) and [LIST](#) partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For [HASH](#) partitioning, the user function employed must return an integer value greater than 0. For [KEY](#) partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->     PARTITION mypart VALUES IN (1,3,5),
->     PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 12.1.17, “CREATE TABLE Syntax”](#).

## 17.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21<sup>st</sup> store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

```

)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

### Note

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 17.2.2, “LIST Partitioning”](#). Also see [Section 12.2.5, “INSERT Syntax”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 17.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```

CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,

```

```

report_status VARCHAR(20) NOT NULL,
report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 12.1.7](#), “`ALTER TABLE Syntax`”, and [Section 17.3](#), “`Partition Management`”, for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 17.4](#), “`Partition Pruning`”, for more information about how this is accomplished.

A variant on this type of partitioning, `RANGE COLUMNS` partitioning, was introduced in MySQL 5.5.0. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See [Section 17.2.3.1](#), “`RANGE COLUMNS partitioning`”, for more information.

**Partitioning schemes based on time intervals.** If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 5.5, you have two options:

1. Partition the table by `RANGE`, and for the partitioning expression, employ a function operating on a `DATE`, `TIME`, or `DATETIME` column and returning an integer value, as shown here:

```

CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

Beginning with MySQL 5.5.1, it is also possible to partition a table by `RANGE` based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```

CREATE TABLE quarterly_report_status (
  report_id INT NOT NULL,
  report_status VARCHAR(20) NOT NULL,
  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
);

```

```

PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

Also beginning with MySQL 5.5.1, any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

### Note

It is also possible in MySQL 5.5.1 and later to use `UNIX_TIMESTAMP(timestamp_column)` as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

2. Partition the table by `RANGE COLUMNS`, using a `DATE` or `DATETIME` column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```

CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE COLUMNS(joined) (
  PARTITION p0 VALUES LESS THAN ('1960-01-01'),
  PARTITION p1 VALUES LESS THAN ('1970-01-01'),
  PARTITION p2 VALUES LESS THAN ('1980-01-01'),
  PARTITION p3 VALUES LESS THAN ('1990-01-01'),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

### Note

The use of partitioning columns employing date or time types other than `DATE` or `DATETIME` is not supported with `RANGE COLUMNS`.

## 17.2.2. `LIST` Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

### Note

In MySQL 5.5, it is possible to match against only a list of integers (and possibly `NULL`—see Section 17.2.7, “How MySQL Partitioning Handles `NULL`”) when partitioning by `LIST`.

However, beginning with MySQL 5.5.0, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 12.1.17, “`CREATE TABLE Syntax`”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)

```

```
);
```

(This is the same table used as a basis for the examples in [Section 17.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LIST(store_id) (
  PARTITION pNorth VALUES IN (3,5,6,9,17),
  PARTITION pEast VALUES IN (1,2,10,11,19,20),
  PARTITION pWest VALUES IN (4,12,13,14,18),
  PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. Beginning with MySQL 5.5.0, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18)`. (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with [RANGE](#) partitioning, it is possible to combine [LIST](#) partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 17.2.6, “Subpartitioning”](#).

Unlike the case with [RANGE](#) partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
  ->   c1 INT,
  ->   c2 INT
  -> )
  -> PARTITION BY LIST(c1) (
  ->   PARTITION p0 VALUES IN (1, 4, 7),
  ->   PARTITION p1 VALUES IN (2, 5, 8)
  -> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3
```

When inserting multiple rows using a single `INSERT` statement, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not:

```
mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT INTO h2 VALUES (4, 7), (3, 5), (6, 0);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3
mysql> SELECT * FROM h2;
+-----+-----+
| c1    | c2    |
+-----+-----+
```

```
+-----+
| 4 | 7 |
+-----+
1 row in set (0.00 sec)
```

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5 Duplicates: 2 Warnings: 0

mysql> SELECT * FROM h2;
+-----+
| c1 | c2 |
+-----+
| 7 | 5 |
| 1 | 9 |
| 2 | 5 |
+-----+
3 rows in set (0.00 sec)
```

MySQL 5.5 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use multiple columns as partitioning keys. For more information, see [Section 17.2.3.2, “LIST COLUMNS partitioning”](#).

### 17.2.3. COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on `RANGE` and `LIST` partitioning that were introduced in MySQL 5.5.0. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both `RANGE COLUMNS` partitioning and `LIST COLUMNS` partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT (INTEGER)`, and `BIGINT`. (This is the same as with partitioning by `RANGE` and `LIST`.)

Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.

- `DATE` and `DATETIME`.

Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY`.

`TEXT` and `BLOB` columns are not supported as partitioning columns.

The discussions of `RANGE COLUMNS` and `LIST COLUMNS` partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see [Section 17.2.1, “RANGE Partitioning”](#), and [Section 17.2.2, “LIST Partitioning”](#), respectively.

#### 17.2.3.1. RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

`RANGE COLUMNS` partitioning differs significantly from `RANGE` partitioning in the following ways:

- `RANGE COLUMNS` does not accept expressions, only names of columns.

- `RANGE COLUMNS` accepts a list of one or more columns.

`RANGE COLUMNS` partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in `RANGE COLUMNS` partitions is also based on comparisons between tuples; this is discussed further later in this section.

- `RANGE COLUMNS` partitioning columns are not restricted to integer columns; string, `DATE` and `DATETIME` columns can also be used as partitioning columns. (See [Section 17.2.3, “COLUMNS Partitioning”](#), for details.)

The basic syntax for creating a table partitioned by `RANGE COLUMNS` is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
  PARTITION partition_name VALUES LESS THAN (value_list)[,
  PARTITION partition_name VALUES LESS THAN (value_list)][,
  ...]
)

column_list:
  column_name[, column_name][, ...]

value_list:
  value[, value][, ...]
```

### Note

Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

In the syntax just shown, *column\_list* is a list of one or more columns (sometimes called a *partitioning column list*), and *value\_list* is a list of values (that is, it is a *partition definition value list*). A *value\_list* must be supplied for each partition definition, and each *value\_list* must have the same number of values as the *column\_list* has columns. Generally speaking, if you use *N* columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of *N* values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
->   a INT,
->   b INT,
->   c CHAR(3),
->   d INT
-> )
-> PARTITION BY RANGE COLUMNS(a,d,c) (
->   PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
->   PARTITION p1 VALUES LESS THAN (10,20,'mmmm'),
->   PARTITION p2 VALUES LESS THAN (15,30,'sss'),
->   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form `(INT, INT, CHAR(3))`, which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
```

```

    a INT,
    b INT
)
PARTITION BY RANGE (a) (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (MAXVALUE)
);

```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```

mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'r1';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             | 0           |
| p1             | 3           |
+-----+-----+
2 rows in set (0.00 sec)

```

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```

CREATE TABLE rc1 (
    a INT,
    b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
    PARTITION p0 VALUES LESS THAN (5, 12),
    PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);

```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```

mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rc1';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0             | 2           |
| p             | p1             | 1           |
+-----+-----+-----+
2 rows in set (0.00 sec)

```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```

mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----+-----+-----+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----+-----+-----+
| 1               | 1               | 0               |
+-----+-----+-----+
1 row in set (0.00 sec)

```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```

SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);

```

For more information about the use of row constructors in MySQL, see [Section 12.2.10.5, “Row Subqueries”](#).

For a table partitioned by **RANGE COLUMNS** using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by **RANGE**. The following **CREATE TABLE** statement creates a table partitioned by **RANGE COLUMNS** using 1 partitioning column:

```
CREATE TABLE rx (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows (5,10), (5,11), and (5,12) into this table, we can see that their placement is the same as it is for the table **r** we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rx';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0              | 0           |
| p             | p1              | 3           |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by **RANGE COLUMNS** where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following **CREATE TABLE** statements is valid:

```
CREATE TABLE rc2 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

CREATE TABLE rc3 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
  PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column **b** is 25 for partition **p0** and 20 for partition **p1**, and the limiting value of column **c** is 100 for partition **p1** and 50 for partition **p2**:

```
CREATE TABLE rc4 (
  a INT,
  b INT,
  c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
  PARTITION p0 VALUES LESS THAN (0,25,50),
  PARTITION p1 VALUES LESS THAN (10,20,100),
  PARTITION p2 VALUES LESS THAN (10,30,50)
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);
```

When designing tables partitioned by **RANGE COLUMNS**, you can always test successive partition definitions by comparing the desired tuples using the **mysql** client, like this:

```
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
```

```

+-----+-----+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)

```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```

mysql> CREATE TABLE rcf (
->   a INT,
->   b INT,
->   c INT
-> )
-> PARTITION BY RANGE COLUMNS(a,b,c) (
->   PARTITION p0 VALUES LESS THAN (0,25,50),
->   PARTITION p1 VALUES LESS THAN (20,20,100),
->   PARTITION p2 VALUES LESS THAN (10,30,50),
->   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
ERROR 1493 (HY000): VALUES LESS THAN VALUE MUST BE STRICTLY INCREASING FOR EACH PARTITION

```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```

mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)

```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See [Section 17.2.3, “COLUMNS Partitioning”](#), for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);

```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```

CREATE TABLE employees_by_lname (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

### Note

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, `'and'` sorts before `'Andersen'`, but when using a collation that is case insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see [Section 9.1, “Character Set Support”](#).

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) (
  PARTITION p0 VALUES LESS THAN ('1970-01-01'),
  PARTITION p1 VALUES LESS THAN ('1980-01-01'),
  PARTITION p2 VALUES LESS THAN ('1990-01-01'),
  PARTITION p3 VALUES LESS THAN ('2000-01-01'),
  PARTITION p4 VALUES LESS THAN ('2010-01-01'),
  PARTITION p5 VALUES LESS THAN (MAXVALUE)
);
```

See [Section 12.1.17, “CREATE TABLE Syntax”](#), for additional information about `PARTITION BY RANGE COLUMNS` syntax.

## 17.2.3.2. LIST COLUMNS partitioning

MySQL 5.5 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see [Section 17.2.3, “COLUMNS Partitioning”](#).)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

Region	Cities
1	Oskarshamn, Högsby, Mönsterås
2	Vimmerby, Hultsfred, Västervik
3	Nässjö, Eksjö, Vetlanda
4	Uppvidinge, Alvesta, Växjö

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```
CREATE TABLE customers_1 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
  PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
  PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
  PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
  PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjö')
);
```

As with partitioning by `RANGE COLUMNS`, you do not need to use expressions in the `COLUMNS ( )` clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with `COLUMNS ( )`.)

It is also possible to use [DATE](#) and [DATETIME](#) columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs [LIST COLUMNS](#) partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```
CREATE TABLE customers_2 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
  PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
    '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
  PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
    '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
  PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
    '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
  PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
    '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ [RANGE](#) or [RANGE COLUMNS](#) partitioning instead. In this case, since the column we wish to use as the partitioning key is a [DATE](#) column, we use [RANGE COLUMNS](#) partitioning, as shown here:

```
CREATE TABLE customers_3 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
  PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
  PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
  PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
  PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);
```

See [Section 17.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

In addition (as with [RANGE COLUMNS](#) partitioning), you can use multiple columns in the `COLUMNS ( )` clause.

See [Section 12.1.17, “CREATE TABLE Syntax”](#), for additional information about `PARTITION BY LIST COLUMNS ( )` syntax.

## 17.2.4. HASH Partitioning

Partitioning by [HASH](#) is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using [HASH](#) partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a `PARTITIONS num` clause, where *num* is a positive integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *expr*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

*expr* must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 17.5, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where *date\_col* is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of *date\_col*, because for every change in the value of *date\_col*, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to *date\_col* is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in *date\_col* produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of *date\_col* and there is no possible change in *date\_col* that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named *int\_col* whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of *int\_col* is not guaranteed to produce a proportional change in the value of the expression. Changing the value of *int\_col* by a given amount can produce by widely different changes in the value of the expression. For example, changing *int\_col* from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of *int\_col* from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation  $y=cx$  where *c* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *num* partitions to use based on the modulus of the result of the user function. In other words, for an expression *expr*, the partition in which the record is stored is partition number *N*, where  $N = \text{MOD}(\text{expr}, \text{num})$ . Suppose that table *t1* is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into *t1* whose *col3* value is '2005-09-15', then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.5 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 17.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

### Note

If a table to be partitioned has a [UNIQUE](#) key, then any columns supplied as arguments to the [HASH](#) user function or to the [KEY](#)'s *column\_list* must be part of that key.

## 17.2.4.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the [LINEAR](#) keyword in the [PARTITION BY](#) clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that *num* is 13. Then [LOG\(2,13\)](#) is 3.7004397181411. [CEILING\(3.7004397181411\)](#) is 4, and *V* = [POWER\(2,4\)](#), which is 16.)

2. Set *N* = *F(column\_list)* & (*V* - 1).
3. While *N* >= *num*:
  - Set *V* = CEIL(*V* / 2)
  - Set *N* = *N* & (*V* - 1)

Suppose that the table *t1*, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into *t1* having the *col3* column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6
```

```
(6 >= 6 is TRUE: additional step required)
N = 6 & CEILING(8 / 2)
  = 6 & 3
  = 2
(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

## 17.2.5. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.5:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tml (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 17.5, “Restrictions and Limitations on Partitioning”](#).

### Note

Tables using the `NDBCLUSTER` storage engine are implicitly partitioned by `KEY`, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the “hidden” primary key gen-

erated by the [NDBCLUSTER](#) storage engine for each MySQL Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an [NDBCLUSTER](#) table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, [PARTITION BY KEY\(\)](#) with no column references—then no explicit primary key is required.

You can observe this partitioning using the [ndb\\_desc](#) utility (with the [-p](#) option).

### Important

For a key-partitioned table, you cannot execute an [ALTER TABLE DROP PRIMARY KEY](#), as doing so generates the error `ERROR 1466 (HY000): FIELD IN LIST OF FIELDS FOR PARTITION FUNCTION NOT FOUND IN TABLE`. This is not an issue for MySQL Cluster tables which are partitioned by [KEY](#); in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 16, MySQL Cluster NDB 7.2](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
  col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using [LINEAR](#) has the same effect on [KEY](#) partitioning as it does on [HASH](#) partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 17.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

## 17.2.6. Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following [CREATE TABLE](#) statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
